General Guidelines (PEDAB-1.0)

ABP.GG.0001.0.A

v2.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms including a detailed history, physical examination, appropriate laboratory studies and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MR, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.
- These guidelines are based upon using advanced imaging to answer specific clinical questions that will affect individual management. Imaging is not indicated if the results will not affect individual management decisions. Standard medical practice would dictate continuing conservative therapy prior to advanced imaging in individuals who are improving on current treatment programs.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the abdomen is not supported. Advanced imaging should only be approved in individuals who have documented active clinical signs or symptoms of disease.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the same body area are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.
- Ultrasound should be the initial imaging study of choice in most children with abdominal conditions and should be done prior to advanced imaging.
  - For those individuals who do require advanced imaging after ultrasound, ultrasound can be very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the individual.
  - CPT® codes vary by body area and presence or absence of Doppler imaging and are included in the table at the beginning of this guideline.

Red Flags

- Children with abdominal pain AND ANY of the following red flag signs or symptoms require additional investigation. The initial ultrasound is not required. Additional labs may be helpful but are not required.
  - Pain that wakes the child from sleep
  - Unexplained fever (T >100.4°F)
  - History of malignancy with a likelihood or propensity to metastasize to abdomen

Click Here to Return to the Main TOC

  - Dysphagia
  - GI bleeding
  - Significant vomiting
  - Elevated WBC per the testing laboratory's range
  - Low WBC (absolute neutrophil count <1000)
  - Guarding, rebound tenderness, or other peritoneal signs
  - Severe chronic diarrhea or nocturnal diarrhea in a toilet-trained child
  - Failure to thrive, involuntary weight loss, or delay in linear growth or pubertal development
  - Family history of inflammatory bowel disease, familial polyposis syndrome, celiac disease, or peptic ulcer disease
  - Abdominal mass, hepatomegaly, and/or splenomegaly on exam
  - Jaundice
  - Perianal disease
  - Suspected or confirmed COVID-19 infection with concern for multisystem inflammatory syndrome in children (MIS-C)
  - Failure to respond to 4 weeks of recent (within 60 days) provider directed conservative care
- See the condition-specific sections for when the above list of exclusionary criteria apply and lead directly to advanced imaging.
- The appropriate advanced imaging for the condition is listed in the condition-specific section.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Pediatric Abdominal Imaging Age Considerations (PEDAB-1.1)

ABP.GG.0001.1.A

v2.0.2026

- Many conditions affecting the abdomen in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases that occur in both pediatric and adult populations, differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals age 18 years old and younger should be imaged according to the Pediatric Abdomen Imaging Guidelines if discussed. Any conditions not specifically discussed in the Pediatric Abdomen Imaging Guidelines should be imaged according to the General Abdomen Imaging Guidelines. Individuals age >18 years old should be imaged according to the General Abdomen Imaging Guidelines, except where directed otherwise by a specific guideline section.

Pediatric Abdomen Imaging Modality General Considerations (PEDAB-1.3)

ABP.GG.0001.3.A
v2.0.2026

- Ultrasound
  - See: **General Guidelines (PEDAB-1.0)**
- MRI
  - MRI Abdomen is generally performed without and with contrast (CPT® 74183) unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years) as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Recent evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If multiple body areas are supported by these guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same session.
  - The presence of surgical hardware or implanted devices may preclude MRI.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - The selection of best examination may require coordination between the provider and the imaging service. CT may be the procedure of choice in these cases.
- CT
    - CT Abdomen typically extends from the dome of the diaphragm to the upper margin of the sacroiliac joints, and CT Abdomen and Pelvis extends from the dome of the diaphragm through the ischial tuberosities.
        - In general, CT Abdomen is appropriate when evaluating solid abdominal organs.
        - In general, CT Abdomen and Pelvis is appropriate when evaluating inflammatory or infectious processes, hematuria, or conditions that appear to involve both the abdomen and the pelvis.
        - In some cases, especially in follow-up of a known finding, it may be appropriate to limit the exam to the region of concern to reduce radiation exposure.
    - The contrast level in pediatric CT imaging is specific to the clinical indication, as listed in the specific guideline sections.
    - CT Abdomen or Abdomen and Pelvis may be medically necessary for further evaluation of abnormalities suggested on prior US or MRI studies.
    - CT may be medically necessary without prior MRI or US as indicated in specific sections of these guidelines.
    - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
    - The selection of the best examination may require coordination between the provider and the imaging service.
- Nuclear Medicine
    - Nuclear medicine studies are commonly used in evaluation of the pediatric kidney and gallbladder. Other less common indications exist as well:
        - Esophageal motility study (CPT® 78258) and/or Gastroesophageal reflux study (CPT® 78262) is medically necessary in the evaluation of gastroesophageal reflux.
    - Nuclear intestinal imaging (preferred code for Meckel's Scan, CPT® 78290) or Gastric mucosa imaging (alternate code for Meckel's scan, CPT® 78261) is medically necessary for the following:
        - Suspected Meckel's diverticulum
        - Gastric mucosa imaging (CPT® 78261) is also medically necessary for:
            - Barrett's esophagus
            - Thoracic masses suspected of containing gastric mucosa
    - Gastric emptying study (CPT® 78264) is medically necessary for evaluation of either suspected delayed or rapid gastric emptying.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- Gastric emptying study with small bowel transit (CPT® 78265) is medically necessary for evaluation of suspected abnormalities in both total and regional times for gastrointestinal transit of the small bowel.
- Gastric emptying study with small bowel and colon transit (CPT® 78266) is medically necessary for evaluation of suspected abnormalities in both total and regional times for gastrointestinal transit to the colon.
- Gastrointestinal bleeding scintigraphy (CPT® 78278) is medically necessary for evaluation of brisk active GI bleeding with indeterminate endoscopy.
- Gastrointestinal protein loss study (CPT® 78282) is medically necessary for decreased serum albumin or globulins and no evidence of GI bleeding.
- Peritoneal-venous shunt patency study (CPT® 78291) is medically necessary for evaluation of shunt patency and function in an individual with ascites.
- Nuclear renal imaging (CPT® 78701, CPT® 78707, CPT® 78708, or CPT® 78709) is medically necessary for evaluation of the following:
  - Renal transplant follow-up
  - Kidney salvage vs. nephrectomy surgical decisions
  - Acute renal failure with no evidence of obstruction on recent ultrasound
  - Chronic renal failure to estimate prognosis for recovery

- 3D Rendering
  - 3D Rendering indications in pediatric abdomen imaging are identical to those in the general imaging guidelines. See: **3D Rendering (Preface-4.1)** in the Preface Imaging Guidelines.

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Generalized Abdominal Pain (PEDAB-2)

ABP.AP.0002.A
v2.0.2026

- Chronic abdominal pain is a common complaint among children and adolescents. Chronic is defined as abdominal pain lasting for over 2 months.
- Functional abdominal pain disorders, including functional abdominal pain and functional dyspepsia (including symptoms of epigastric pain, burning, postprandial fullness, early satiety), are conditions in which there is no structural or organic disease.
- Ultrasound Abdomen (CPT® 76700 or CPT® 76705) is medically necessary as the initial imaging for children with no red flag signs or symptoms, normal physical examination, and normal laboratory studies (preliminary labs may include CBC, electrolytes, lipase, amylase, urinalysis, ESR, CRP, LFTs, and/or stool for blood and stool culture if diarrhea)
  - Gastroenterology (GI) specialist evaluation or consultation is helpful in determining the need for advanced imaging in these cases.
  - CT Abdomen (CPT® 74160) with contrast or CT Abdomen and Pelvis (CPT® 74177) with contrast is medically necessary if there are any red flag signs or symptoms (as listed in **General Guidelines (PEDAB-1.0)**).
- Children with abdominal pain that can be localized to a particular area of the abdomen should be imaged according to the relevant guideline section:
  - **Right Lower Quadrant Pain (PEDAB-3)**
  - **Flank Pain, Renal Stone (PEDAB-4)**
  - **Right Upper Quadrant Pain (PEDAB-8)**
  - **Left Upper Quadrant Pain (PEDAB-25)**
  - **Left Lower Quadrant Pain (PEDAB-29)**

Health Equity Considerations

Abdominal pain is a common reason for Emergency Department (ED) assessment in the pediatric population. Children with abdominal pain are assessed for conditions that require urgent evaluation and treatment such as appendicitis, intussusception, volvulus, or adhesion.[11] Appendicitis is an important diagnostic differential to consider for acute abdominal pain for potential urgent or emergent abdominal surgery. Health outcomes are dependent on appropriate diagnosis and treatment.[12]

Health disparities influence children's healthcare as they may have long-term impacts on important outcomes such as health as an adult, educational attainment, and economic success.[13] Health disparities facing minority children with abdominal pain include lack of advanced imaging such as ultrasound or computed tomography (CT) scan, and

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

having a higher appendiceal perforation rate.[14] Studies also showed that racial and ethnic minorities are less likely to receive opioid analgesia even when symptoms are severe.[15] Lastly, non-Hispanic Black and Hispanic individuals were more likely than non-Hispanic whites to have a prolonged length of stay.[16] Solutions to health disparity issues include continued data and research, policy interventions, and individual and family engagement.

Right Lower Quadrant Pain (PEDAB-3)

ABP.RT.0003.A
v2.0.2026

- The presence of any red flag findings per **General Guidelines (PEDAB-1.0)** precludes adjudication based on any other criteria.
- Ultrasound (CPT® 76700 or CPT® 76705) is medically necessary as the initial examination. If positive or negative for uncomplicated appendicitis, no further imaging is necessary.
  - If the appendix is not visualized on ultrasound and the white blood cell count is not elevated, no further imaging is necessary in nearly all cases, although the referring physician should make the final determination of the need for advanced imaging.
- CT Abdomen and Pelvis with contrast (CPT® 74177), MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195), or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary for any of the following:
  - Individuals who are overweight (BMI ≥85th percentile for age)
  - Insufficient local ultrasound expertise exists
  - Ultrasound findings are inconclusive
  - Clinical suspicion of or initial imaging suggestive of complication (e.g., abscess, bowel obstruction)
- If the appendix is absent, follow guidelines in: **Generalized Abdominal Pain (PEDAB-2)**

Flank Pain, Renal Stone (PEDAB-4)

ABP.US.0004.A
v2.0.2026

- The presence of any red flag findings per **General Guidelines (PEDAB-1.0)** precludes adjudication based on any other criteria.
- Flank Pain imaging indications in pediatric individuals are very similar to those for adult individuals. See: **Flank Pain, Rule Out or Known Renal/Ureteral Stone (AB-4)** in the Abdomen Imaging Guidelines.
  - Ultrasound (CPT® 76770 or CPT® 76775) is the medically necessary initial study in children.
  - CT Abdomen and Pelvis without contrast (CPT® 74176) is medically necessary if ultrasound is inconclusive.
  - MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast is medically necessary if CT is inconclusive or if significant concern for radiation exposure from frequent CT use for a particular individual.
  - If hematuria is present, see: **Hematuria (PEDAB-7)** for imaging guidelines.
- Nuclear kidney imaging (CPT® 78707, CPT® 78708, CPT® 78709, or CPT® 78803) is medically necessary for evaluation of recurrent flank pain when CT and ultrasound are non-diagnostic, or for suspected obstructive uropathy.

Upper Urinary Tract (PEDAB-5.1)

ABP.UT.0005.1.A
v2.0.2026

- Ultrasound evaluation (CPT® 76770 or CPT® 76775) is the medically necessary initial imaging for all children with first-time upper urinary tract infection to diagnose hydronephrosis, pyelonephritis, or congenital renal anomaly.
  - If hydronephrosis is present, this should be further evaluated with voiding cystourethrography (VCUG), to evaluate for vesicoureteral reflux.
    - In boys, this is generally accomplished using fluoroscopic imaging and iodinated contrast to exclude urethral abnormalities.
    - In girls, Ureteral Reflux Study (Radiopharmaceutical Voiding Cystogram) (CPT® 78740) or fluoroscopic VCUG may be performed.
    - Contrast Enhanced Voiding Urosonography (CeVUS) may also be utilized at institutions with expertise in this modality.
- Diuretic renography using Tc-99m MAG 3 (CPT® 78707, CPT® 78708, or CPT® 78709) is medically necessary for:
  - differentiating a dilated non-obstructed urinary system from a true stenosis (e.g., UPJ obstruction; ureteral-vesical junction [UVJ] obstruction)
  - quantifying renal parenchymal function
  - ultrasound findings that are compatible with a multicystic dysplastic kidney to evaluate function of the affected kidney or a ureteral-pelvic junction (UPJ) obstruction of the contralateral kidney
  - diagnostic evaluation of upper tract dilatation when VCUG is negative
  - renal function evaluation in individuals with hydronephrosis
- CT is sensitive in diagnosing pyelonephritis and has a role in evaluation of renal abscess or unusual complications such as xanthogranulomatous pyelonephritis but has no role in the routine evaluation of UTI.
  - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary to evaluate the entire genitourinary tract for congenital abnormalities of distal tracts in complicated pyelonephritis.
- Magnetic resonance urography (MRU) (CPT® 74183 and CPT® 72197), is not a first-line test for the routine evaluation of a UTI but is medically necessary (where available) for investigation of a dilated upper urinary tract.
  - NOTE: MRU requires sedation in young children.
  - MRU can also quantitate renal function.
- Technetium-99m-dimercaptosuccinic acid (Tc-99m DMSA) scintigraphy (CPT® 78700, CPT® 78701, or CPT® 78803), is sensitive for evaluation of renal cortical damage.
  - DMSA scintigraphy is medically necessary for:
    - individuals with atypical or recurrent febrile acute urinary tract infections

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Atypical findings may include poor response to antibiotics, elevated creatinine, poor urine stream, or non E-coli organism.
- individuals with febrile urinary tract infections older than 5 years of age with known vesicoureteral reflux
- detection of post-pyelonephritic renal scarring at least 6 months after the documented upper tract UTI in high-risk individuals with recurrent UTIs

- Radiopharmaceutical nuclear medicine imaging (CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, CPT® 78830, CPT® 78831, or CPT® 78832) is medically necessary for evaluation of suspected pyelonephritis or diffuse interstitial nephritis.
- Nuclear non-imaging renal function study (CPT® 78725) is a quantitative study that can be used to evaluate renal function.
- US Kidneys and bladder (CPT® 76770 or CPT® 76775) (preferred) and/or Voiding Cystourethrography (CPT® 78740) are medically necessary for children with atypical (poor response to antibiotics within 48 hours, sepsis, poor urine stream, raised creatinine, or non-E. coli UTI) or recurrent febrile UTI.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Lower Urinary Tract (PEDAB-5.2)

ABP.UT.0005.2.A

v2.0.2026

- Ultrasound evaluation (CPT® 76770 or CPT® 76775) is medically necessary as the initial imaging for all children with first time UTI to diagnose hydronephrosis, pyelonephritis, or congenital renal anomaly.
  - Fluoroscopic Voiding cystourethrography (VCUG) is medically necessary for detection of possible vesico-ureteral reflux (VUR) in neonates or young children when hydronephrosis is seen on ultrasound.
- The American Academy of Pediatrics clinical practice guidelines no longer recommend routine VCUG for females, 2 to 24 months of age, after the first febrile UTI.
  - The current recommendation is to postpone the VCUG until the second febrile UTI UNLESS there are:
    - atypical or complex clinical circumstances
    - renal/bladder ultrasound findings that reveal hydronephrosis, scarring, or obstructive uropathy
- Vesicoureteral Reflux (VUR)
  - Fluoroscopic VCUG is typically performed for diagnosis and grading of VUR, and is the medically necessary first modality used for diagnosis.
  - Ureteral Reflux Study (Radiopharmaceutical Voiding Cystogram) (CPT® 78740), fluoroscopic VCUG, or CeVUS are medically necessary for follow up imaging of VUR.
- Male individuals with first UTI should be evaluated with fluoroscopic VCUG studies rather than radionuclide cystography, to visualize the male urethra for possible abnormalities such as posterior urethral valves, strictures, or diverticula.
- For female individuals, radionuclide cystography (CPT® 78740) or fluoroscopic VCUG are medically necessary as the initial study.
- MR urography is medically necessary for evaluation of ectopic distal ureteral insertion, or other complex lower urinary tract anatomy.
- Siblings of individuals with known vesicoureteral reflux can undergo Ureteral Reflux Study (Radiopharmaceutical Voiding Cystogram) (CPT® 78740) if they have renal scarring on ultrasound or history of UTI and no prior evaluation for VUR.

Pediatric Acute Gastroenteritis (PEDAB-6)

ABP.GE.0006.A
v2.0.2026

- Advanced imaging is not medically necessary in pediatric acute gastroenteritis unless there is a concern for diagnosis other than acute gastroenteritis. See specific symptom/diagnosis sections listed below.
- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if abdominal red flag symptoms are present as listed in **General Guidelines (PEDAB-1.0)**.
- Additional imaging studies will depend on the specific symptoms. See the following sections for additional imaging guidelines:
  - **Generalized Abdominal Pain (PEDAB-2)** in the Pediatric Abdomen Imaging Guidelines
  - **Right Lower Quadrant Pain (PEDAB-3)** in the Pediatric Abdomen Imaging Guidelines
  - **Right Upper Quadrant Pain (PEDAB-8)** in the Pediatric Abdomen Imaging Guidelines
  - **Inflammatory Bowel Disease, Crohn Disease, or Ulcerative Colitis (PEDAB-9)** in the Pediatric Abdomen Imaging Guidelines
  - **Constipation, Diarrhea, and Irritable Bowel Syndrome (PEDAB-12)** in the Pediatric Abdomen Imaging Guidelines
  - **Abdominal Mass (PEDAB-13)** in the Pediatric Abdomen Imaging Guidelines
  - **Left Upper Quadrant (PEDAB-25)** in the Pediatric Abdomen Imaging Guidelines
  - **Intussusception (PEDAB-27)** in the Pediatric Abdomen Imaging Guidelines
  - **Bowel Obstruction (PEDAB-28)** in the Pediatric Abdomen Imaging Guidelines

Hematuria (PEDAB-7)

ABP.HH.0007.A
v2.0.2026

Hematuria is a relatively common complaint in pediatric individuals, and the imaging considerations are different from those occurring in adult individuals.

- Ultrasound kidneys (CPT® 76770 or CPT® 76775) and bladder (CPT® 76856 or CPT® 76857) are medically necessary for asymptomatic gross hematuria or microscopic hematuria with proteinuria present.
- Imaging is not considered medically necessary for asymptomatic microscopic hematuria without proteinuria.
- For painful hematuria and no recent trauma, ANY of the following studies are medically necessary:
  - CT Abdomen and Pelvis without contrast (CPT® 74176)
  - Ultrasound kidneys (CPT® 76770 or CPT® 76775)
  - Ultrasound bladder (CPT® 76856 or CPT® 76857)
- For hematuria and recent trauma, the following studies are medically necessary:
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
- CT Cystography (CT Pelvis with bladder contrast – CPT® 72193) is medically necessary if gross hematuria is present and pelvic fracture or traumatic bladder injury is suspected.
- 3-D reconstruction (CPT® 76377 or CPT® 76376) is medically necessary, if requested, for surgical planning.

Right Upper Quadrant Pain (PEDAB-8)

ABP.RU.0008.A
v2.0.2026

- The presence of any red flag findings per **General Guidelines (PEDAB-1.0)** precludes adjudication based on any other criteria.
- Right upper quadrant pain imaging indications in pediatric individuals are very similar to those for adult individuals. See: **Abdominal Pain (AB-2)** in the Abdomen Imaging Guidelines.
  - US Abdomen (CPT® 76700) and/or Nuclear medicine imaging of the hepatobiliary system (HIDA scan, CPT® 78226 or CPT® 78227) is medically necessary for initial diagnosis of:
    - suspected acute cholecystitis or acalculous cholecystitis (symptoms may include RUQ pain with fever, elevated white blood cell count, positive Murphy sign).
    - suspected gallstones and bile duct obstruction (symptoms may include RUQ pain, no fever, normal white blood cell count).
    - Ultrasound results are not needed prior to nuclear medicine imaging of the hepatobiliary system (HIDA scan, CPT® 78226 or CPT® 78227).
  - MRI Abdomen with and without contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160) is medically necessary when either US or NM is equivocal.
  - In individuals with complaints of RUQ pain with no fever and an ultrasound shows only gallstones, MRI Abdomen without contrast (CPT® 74181), MRI Abdomen without and with contrast (CPT® 74183), or Nuclear medicine imaging of the hepatobiliary system (HIDA scan, CPT® 78226 or CPT® 78227) is medically necessary to exclude other sources of pain.

Inflammatory Bowel Disease, Crohn Disease, or Ulcerative Colitis (PEDAB-9)

ABP.IB.0009.A

v2.0.2026

- Enterography is the medically necessary advanced imaging study for individuals with inflammatory bowel disease (IBD).
  - MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195) is generally preferred over CT when possible to avoid radiation exposure for children.

Children with Suspected Crohn Disease

Clinical features including weight loss, loose stools, vomiting, and intermittent abdominal pain. Small bowel imaging can provide important information to guide treatment relating to presence, severity, and extent of Crohn's disease and its complications. Initial evaluation typically includes laboratory evaluation and upper and lower endoscopy.

- MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195), CT Enterography (CPT® 74177), or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary for ANY of the following:
  - To detect severity and distribution of inflammatory changes
  - To identify complications (such as fistulizing disease or abscess formation)
- MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195) or CT Enterography (CPT® 74177) is medically necessary for evaluation of chronic abdominal pain associated with diarrhea due to concern for inflammatory bowel disease if:
  - there is a positive family history of inflammatory bowel disease, **OR**
  - there are endoscopy or colonoscopy findings suggestive of inflammatory bowel disease, **OR**
  - elevated inflammatory markers (fecal lactoferrin ≥4.0ug/g, CRP >0.5mg/dL, or fecal calprotectin ≥50ug/g), **OR**
  - diagnosis is still in doubt after colonoscopy and evaluation of inflammatory markers, and Crohn's disease is suspected.
- MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195) or CT Enterography (CPT® 74177) is medically necessary prior to endoscopy if requested by or in consultation with the physician who will be performing the endoscopy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI Pelvis with contrast (CPT® 72196) or MRI Pelvis without and with contrast (CPT® 72197) is medically necessary for the following:
  - Concern for perianal fistula or abscess
- See: **IBD (Crohn's Disease or Ulcerative Colitis) (AB-23.1)** in the Abdomen Imaging Guidelines for additional information regarding serologic markers

Children with Established IBD

- MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195), CT Enterography (CPT® 74177), or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197), is medically necessary for ANY of the following:
  - Monitoring response to disease-modifying treatment on an annual basis or when treatment change is being considered
  - Monitoring post-operative recurrence
  - Individuals with new or worsening symptoms or suspected complications including abscess, perforation, fistula, or obstruction
- CT Abdomen and Pelvis with contrast (CPT 74177) is medically necessary if requested (instead of CTE or MRE) for ANY of the following:
  - New or worsening symptoms
  - Suspected complications including abscess, perforation, fistula, or obstruction
- MRI Pelvis with contrast (CPT® 72196) or MRI Pelvis without and with contrast (CPT® 72197) is medically necessary for the following:
  - Concern for perianal fistula or abscess

ABP.OP.0011.A
v2.0.2026

- Any of the following are medically necessary in individuals with suspected postoperative complications (e.g., bowel obstruction, abscess, anastomotic leak, etc.):
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
  - Ultrasound Abdomen (CPT® 76700 or CPT® 76705)
  - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
  - MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195)
    - Because MRI may not be practical for the timely evaluation of post-operative abscesses, MRI should only replace CT when the study can be completed in a similar time frame as CT.
- Radiopharmaceutical nuclear medicine imaging (CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, CPT® 78830, CPT® 78831, or CPT® 78832) is medically necessary for evaluation of any of the following:
  - Peritonitis
  - Postoperative fever without localizing signs or symptoms
- Beyond 60 days post-operatively, see: **Generalized Abdominal Pain (PEDAB-2)**.

Constipation, Diarrhea, and Irritable Bowel Syndrome (PEDAB-12)

ABP.DC.0012.A
v2.0.2026

- Constipation and diarrhea are extremely common complaints in children. The overwhelming majority of individuals do not require advanced imaging for evaluation of constipation or diarrhea.
- Irritable bowel is rare in young children, but more common in adolescents. The overwhelming majority of individuals do not require advanced imaging for evaluation of irritable bowel syndrome.
  - In most cases, causes of constipation can be excluded based on a careful history and physical examination. Advanced Imaging should be performed if warning signs of other diseases are present.
- Constipation associated with additional signs or symptoms:
  - CT Abdomen (CPT® 74160) or Abdomen and Pelvis (CPT® 74177) with contrast is medically necessary if there are any red flag signs or symptoms (as listed in **General Guidelines (PEDAB-1.0)**)
  - Clinical suspicion of tethered cord (e.g., abnormal physical findings over the spine, abnormal neurological exam, or symptoms refractory to provider-directed treatment for at least 3 months), see: **Spinal Dysraphism and Tethered Cord (PEDSP-4)** in the Pediatric and Special Populations Spine Imaging Guidelines.
- Diarrhea associated with additional signs or symptoms:
  - CT Abdomen (CPT® 74160) with contrast or CT Abdomen and Pelvis (CPT® 74177) with contrast is medically necessary if there are any red flag signs or symptoms (as listed in **General Guidelines (PEDAB-1.0)**).
  - See: **Inflammatory Bowel Disease, Crohn Disease, or Ulcerative Colitis (PEDAB-9)** for concerns regarding suspected inflammatory bowel disease.
- Irritable bowel syndrome associated with additional signs or symptoms:
  - CT Abdomen (CPT® 74160) with contrast or CT Abdomen and Pelvis (CPT® 74177) with contrast is medically necessary if there are any red flag signs or symptoms (as listed in **General Guidelines (PEDAB-1.0)**).
- Hirschsprung disease:
  - MRI Pelvis without and with contrast (CPT® 72197) is medically necessary post-operatively in individuals who have signs of complications related to treatment to assess the position of the pulled-through bowel, the sphincter muscles, and the area of the posterior urethra.

Abdominal Wall Mass (PEDAB-13.1)

ABP.AM.0013.1.A

v2.0.2026

- For initial imaging of a newly discovered abdominal wall mass, ANY of the following studies are medically necessary:
  - Ultrasound (CPT® 76700 or CPT® 76705)
  - MRI Abdomen without contrast (CPT® 74181) or without and with contrast (CPT® 74183)
  - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) may be added to MRI Abdomen if below the umbilicus.
- If ultrasound and/or MRI are inconclusive or insufficient for preoperative planning, ANY of the following studies are medically necessary:
  - CT Abdomen with contrast (CPT® 74160) or without contrast (CPT® 74150)
  - CT Abdomen and Pelvis with contrast (CPT® 74177) or without contrast (CPT® 74176) if below the umbilicus

Intra-Abdominal Mass (PEDAB-13.2)

ABP.AM.0013.2.A

v2.0.2026

- Ultrasound (CPT® 76700) is medically necessary as the initial imaging study for children with an intra-abdominal mass.
  - US with Doppler (CPT® 93975) is medically necessary to evaluate vascular supply.
- Additional imaging studies will be determined by the results of the ultrasound, and will depend on the location and organ involvement associated with the mass as well as history, physical exam, and laboratory findings. See the following sections for additional imaging guidelines:
  - **General Guidelines (PEDONC-1)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Pediatric Lymphomas (PEDONC-5)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Neuroblastoma (PEDONC-6)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Pediatric Renal Tumors (PEDONC-7)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Pediatric Germ Cell Tumors (PEDONC-10)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Pediatric Liver Tumors (PEDONC-11)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Pediatric Adrenocortical Carcinoma (PEDONC-14)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - **Liver Lesion Characterization (PEDAB-15)**
  - **Adrenal Lesions (PEDAB-17)**
  - **Indeterminate Renal Lesion (PEDAB-19)**
  - **Spleen (PEDAB-26)**

Renovascular Hypertension and Other Secondary Causes of Hypertension (PEDAB-14)

ABP.RH.0014.A
v2.0.2026

- Clinical evaluation for suspected hypertension should include repeated blood pressure measurements (generally ≥3 measurements).
  - Trained health care professionals in the office setting should make a diagnosis of hypertension (HTN) if a child or adolescent has auscultatory-confirmed blood pressure (BP) readings ≥95th percentile at 3 different visits.
  - Blood pressure can be obtained in-clinic, at home, or by using a wearable ambulatory blood pressure measurement (ABPM) device that records blood pressure at frequent intervals during normal activities and is downloaded later for computer analysis.

For Children Aged 1-<13 years	For Children Aged ≥13 years
Normal BP: <90th Percentile	Normal BP: <120/<80 mm Hg
Elevated BP: ≥90th percentile to <95th percentile or 120/80 mm Hg to <95th percentile (whichever is lower)	Elevated BP: 120/<80 to 129/<80 mm Hg
Stage 1 HTN: ≥95th percentile to <95th percentile + 12 mmHg, or 130/80 to 139/89 mm Hg (whichever is lower)	Stage 1 HTN: 130/80 to 139/89 mm Hg
Stage 2 HTN: ≥95th percentile + 12 mm Hg, or ≥140/90 mm Hg (whichever is lower)	Stage 2 HTN: ≥140/90 mm Hg

- ANY of the following studies are medically necessary for initial evaluation of a pediatric individual with suspected secondary hypertension:
  - Doppler or Duplex Ultrasound (CPT® 93975 or CPT® 93976)
  - Complete retroperitoneal Ultrasound (CPT® 76770)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Captopril renography (CPT® 78709) has largely been abandoned in clinical practice, replaced by CTA and MRA Abdomen, but may be supported for unusual circumstances.

Other considerations for imaging evaluation:

- CTA Abdomen (CPT® 74175) or MRA Abdomen (CPT® 74185) is medically necessary for pediatric individuals with hypertension to exclude fibromuscular dysplasia or other blood-flow restricting lesions of the renal arteries and suprarenal aorta.
- Children with high clinical suspicion for renin-mediated hypertension should undergo additional imaging whether Doppler US findings are positive or negative due to poor sensitivity for detecting distal intrarenal or accessory renal artery stenosis. CTA (CPT® 74175) has high sensitivity and specificity, and is medically necessary for these individuals.
- Echocardiography (CPT® 93306) is medically necessary at initial evaluation to screen for cardiac abnormalities, coarctation of the aorta, and end-organ damage such as left ventricular hypertrophy.
- Nuclear renal imaging (CPT® 78707, CPT® 78708, or CPT® 78709) is medically necessary for evaluation of the following:
  - Severe hypertension with progressive renal insufficiency or failure to respond to three-drug therapy
  - Malignant or accelerated hypertension
  - Acute worsening of previously stable hypertension
  - Diastolic BP >100 in an individual <35 years old
  - New onset severe hypertension
  - Hypertension in presence of asymmetric kidneys
  - Hypertension in presence of acute elevation in creatinine either unexplained or after treatment with ACE inhibitor
  - Abdominal bruit
  - Recurrent acute pulmonary edema and hypertension
  - Hypokalemia with normal or elevated plasma renin level in absence of diuretic therapy
  - Hypertension with known neurofibromatosis

Liver Lesion Characterization (PEDAB-15)

ABP.LL.0015.A
v2.0.2026

- *High-risk individuals:
  - Prematurity
  - Low birth weight
  - Underlying chronic liver disease
  - Beckwith-Weidman syndrome
  - Familial adenomatous polyposis
  - Trisomy 18
  - Portosystemic shunts
  - Aicardi syndrome
  - Hereditary tyrosinemia
  - Bile salt export pump deficiency
- Pediatric-specific imaging considerations includes:
  - US Abdomen (CPT® 76700 or CPT® 76705) is medically necessary as the initial study in children. MRI is preferred over CT when possible to reduce radiation exposure.
- Liver lesion discovered on US:
  - Any high-risk individual*
    - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160)
  - Indeterminate liver lesion <3cm
    - Contrast-Enhanced US (CEUS, CPT® 76978, CPT® 76979)
    - If after Contrast-Enhanced US the lesion remains indeterminate or not fully characterized, or if Contrast-Enhanced US is not available:
      - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160)
  - Indeterminate liver lesion >3cm
    - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160)
- Liver lesion discovered on CT (non-contrast or single-contrast) or non-contrast MRI
  - Indeterminate Liver Lesion <3cm
    - Contrast-Enhanced US (CEUS, CPT® 76978, CPT® 76979)
    - If, after Contrast-Enhanced US, the lesion remains indeterminate or not fully characterized, or if Contrast-Enhanced US is not available:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

        - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160)
    - Indeterminate Liver Lesion >3cm
        - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160)
- For the imaging of specific focal liver lesions:
    - Suspected hepatic adenoma:
        - CT Abdomen (CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) every 6 months for 2 years, and then annually, to establish any growth patterns and assess for malignant transformation.
    - Hepatic Hemangioma
        - Limited US Abdomen in 6-12 months
            - If stable or decreasing in size: Surveillance 6-12 months until 2 years. After 2 years, no further follow-up is considered medically necessary unless it becomes symptomatic
            - If increasing in size: follow-up 3-6 months or biopsy
            - See below for pre-operative considerations
    - Focal Nodular Hyperplasia (FNH):
        - MRI Abdomen (CPT® 74183) or CT Abdomen (CPT® 74160 or CPT® 74170) to confirm a diagnosis of FNH. The use of Eovist contrast is often diagnostic in differentiating FNH from other lesions seen on MRI or CT.
        - Additional follow-up is limited abdominal US in 6-12 months
            - If stable or decreasing in size: Surveillance 6-12 months until 2 years. After 2 years, no further follow-up is considered medically necessary unless it becomes symptomatic.
            - In adolescent females diagnosed with FNH who are continuing to use oral contraceptives: Additional follow-up is annual US for 2 to 3 years. Follow-up with CT or MRI is medically necessary if the lesion is not adequately visualized on US.
            - If increasing in size: follow-up 3-6 months or biopsy
    - Hepatic cysts:
        - Asymptomatic, simple cysts
            - Limited US Abdomen in 6-12 months
            - If stable or decreasing in size: Surveillance 6-12 months until 2 years. After 2 years, no further follow-up is considered medically necessary unless it becomes symptomatic
            - If increasing in size: follow-up 3-6 months or biopsy
        - For complicated cysts (US shows internal septations, fenestrations, calcifications, irregular walls, as well as the presence of daughter cysts):

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - MRI Abdomen (CPT® 74183) or CT Abdomen (CPT® 74160 or CPT® 74170) is medically necessary
- Additional scenarios and follow-up imaging for an indeterminate lesion:
  - Indeterminate lesion <1cm in high-risk individuals* on US, CT, or unenhanced MRI not specifically dealt with in the above guidelines:
    - If **biopsy cannot be performed**, follow-up MRI is medically necessary at 3-6 months. Additional imaging in this setting can be considered on an individual basis. This timeframe would also apply if the lesion is indeterminate and an MRI with Eovist is requested for further evaluation in this setting.
- Nuclear medicine liver imaging (ONE of CPT® codes: CPT® 78201, CPT® 78202, CPT® 78803, CPT® 78215, or CPT® 78216) is medically necessary for the following when ultrasound, CT, and MRI are unavailable or contraindicated:
  - Evaluation of liver mass, trauma, or suspected focal nodular hyperplasia (FNH)
  - Differentiation of hepatic hemangioma from FNH
  - Diffuse hepatic disease or elevated liver function tests
  - Suspected accessory spleen (CPT® 78215 or CPT® 78216 only)

Background and Supporting Information

- For liver lesions in children, it is important to differentiate between benign incidental versus malignant lesions.

Risk factors for malignant liver tumors in children

Hepatoblastoma	Hepatocellular carcinoma
◦ Prematurity	◦ Liver cirrhosis
◦ Low birth weight	◦ Chronic hepatitis B and C
◦ BWS and other overgrowth syndromes	◦ Hereditary tyrosinemia
◦ Familial adenomatous polyposis	◦ Portosystemic shunts
◦ Trisomy 18	◦ Bile salt export pump deficiency
◦ Portosystemic shunts	
◦ Aicardi syndrome

Pediatric Liver Failure and Cirrhosis (PEDAB-16.1)

ABP.LD.0016.1.A
v2.0.2026

- Elevated liver function testing imaging indications in pediatric individuals are very similar to those for adult individuals. See: **Abnormal Liver Chemistries (AB-30)** in the Abdomen Imaging Guidelines.
- Causes of liver failure or cirrhosis in pediatric individuals are different from adults, and are frequently idiopathic, but commonly due to ONE of the following:
  - Biliary dysfunction (biliary atresia, cystic fibrosis, etc.)
  - Metabolic disease
  - Post-infectious
- Liver ultrasound (CPT® 76700) with duplex Doppler (CPT® 93975) is medically necessary as an initial study for individuals prior to approving CT or MRI for pediatric individuals.
  - MRI Abdomen without and with contrast (CPT® 74183) is indicated for evaluation of ultrasound findings that are inconclusive or technically limited, and is preferred over CT when possible to reduce radiation exposure.
- Repeat liver ultrasound (CPT® 76705) with duplex Doppler (CPT® 93975 or CPT® 93976) is medically necessary in pediatric individuals in the following circumstances:
  - Annually, for known chronic liver dysfunction or cirrhosis of any cause
  - New or worsening findings on history, physical exam, or laboratory results that suggest progression of liver disease
  - Portal venous congestion or portal hypertension is suspected
- Nuclear medicine liver imaging (ONE of CPT® codes: CPT® 78201, CPT® 78202, CPT® 78803, CPT® 78215, or CPT® 78216) is rarely performed, but is medically necessary for the following when ultrasound, CT, and MRI are unavailable or contraindicated:
  - Diffuse hepatic disease or elevated liver function tests

Biliary Disease (PEDAB-16.2)

ABP.LD.0016.2.A

v2.0.2026

- The definition of conjugated hyperbilirubinemia is serum conjugated bilirubin >1mg/dL if total bilirubin <5.0 or greater than 20 percent of total bilirubin if total bilirubin >5.0mg/dL. Obstructive causes of liver disease need to be evaluated. Additional labs may include total and fractionated bilirubin, AST, ALT, Alk Phos, GGT, and/or urinalysis.
- Ultrasound Abdomen (CPT® 76700 or CPT® 76705) is medically necessary as the initial imaging study.
  - Advanced imaging such as CT, MRI is rarely medically necessary unless otherwise indicated below.
- After initial ultrasound:
  - If biliary atresia is suspected:
    - Hepatobiliary system imaging (HIDA scan) is medically necessary if requested by surgeon before liver biopsy.
  - If choledochal cyst is suspected:
    - CT Abdomen with contrast (CPT® 74160) or MRI/MRCP (CPT® 74183 or CPT® 74181) is medically necessary.
    - For preoperative assessment: MRI/MRCP (CPT® 74183 or CPT® 74181) is medically necessary.
  - If primary biliary disease such as primary sclerosing cholangitis or primary biliary cholangitis is suspected:
    - CT Abdomen with contrast (CPT® 74160) or MRI/MRCP (CPT® 74183 or CPT® 74181) is medically necessary.
- Follow-up of resected choledochal cysts (types I and IV, and type V not treated by transplantation):
  - Immediately after resection:
    - Ultrasound Abdomen (CPT® 76700 or CPT® 76705) AND MRI Abdomen with cholangiography (CPT® 74183) is medically necessary.
  - Years 1-20 post-resection:
    - Ultrasound Abdomen (CPT® 76700 or CPT® 76705), biannually
      - MRI Abdomen with cholangiography (CPT® 74183) is medically necessary on every 3-year schedule (in lieu of ultrasound) for any of the following:
        - Ultrasound is not feasible due to body habitus
        - Ultrasound is unavailable
  - Years 21-40 post-resection:
    - Ultrasound Abdomen (CPT® 76700 or CPT® 76705), every 3 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI Abdomen with cholangiography (CPT® 74183) is medically necessary on every 4-year schedule (in lieu of ultrasound) for any of the following:
  - Ultrasound is not feasible due to body habitus
  - Ultrasound is unavailable

◦ Residual cystic tissue is present following resection:
▪ Ultrasound Abdomen (CPT® 76700 or CPT® 76705), annually

Liver Elastography (PEDAB-16.3)

ABP.LD.0016.3.A

v2.0.2026

- The following is medically necessary for initial staging of liver fibrosis in suspected chronic liver disease:
  - Transient Elastography or Vibration-Controlled Transient Elastography (VCTE, e.g. Fibroscan) (CPT® 91200) is the initial imaging modality.
  - Magnetic Resonance Elastography (MRE, CPT® 76391) is medically necessary for ANY of the following:
    - Transient Elastography failure despite use of an XL-probe, OR BMI ≥30
    - Conflict between clinical picture and transient elastography results

Adrenal Lesions (PEDAB-17)

ABP.AC.0017.A

v2.0.2026

- Adrenal masses in infants and young children usually present as palpable abdominal masses or are detected on in utero US. In the neonates, the common masses are adrenal hemorrhage and neuroblastoma. Abdominal US is the medically necessary initial imaging study.
  - If an adrenal mass is detected, it can often be adequately evaluated with short interval follow-up retroperitoneal ultrasound (CPT® 76770) in 7 to 10 days.
    - If repeat ultrasound is concerning for neuroblastoma or there is high clinical concern for neuroblastoma, MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen without and with contrast (CPT® 74170) are medically necessary to confirm the diagnosis. MRI is preferred over CT when possible to reduce radiation exposure. If these studies, confirm neuroblastoma ^{123}I-Metaiodobenzylguanidine (MIBG) scintigraphy is medically necessary for staging.
  - Neuroblastoma is the most common primary adrenal tumor in pediatric individuals between day 1 and 5 years of age. See: **Neuroblastoma (PEDONC-6)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Additional adrenal imaging considerations include the following:
  - Adrenal Nuclear Imaging of the cortex and/or medulla (CPT® 78075) is medically necessary for the following:
    - Distinguishing adrenal adenoma from adrenal hyperplasia.
    - Evaluation of suspected pheochromocytoma or paraganglioma.
      - MIBG preferred (ONE of CPT® codes: CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, or CPT® 78804).
      - For known pheochromocytoma or paraganglioma, see: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)** in the Oncology Imaging Guidelines.
    - Evaluation of suspected neuroblastoma, ganglioneuroblastoma, or ganglioneuroma.
      - MIBG preferred (ONE of CPT® codes: CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, or CPT® 78804 or hybrid SPECT/CT CPT® 78830, CPT® 78831, or CPT® 78832), see: **Neuroblastoma (PEDONC-6)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Transfusion-Associated (Secondary) Hemochromatosis (PEDAB-18.2)

ABP.HC.0018.2.A

v2.0.2026

- Transfusion-associated hemochromatosis is a common complication of exposure to repeated red blood cell transfusions. This can occur in any individual with exposure to >20 transfusion episodes, but is most common among sickle cell disease, thalassemia, bone marrow failure (aplastic anemia, Fanconi anemia, etc.), oncology patients, and hematopoietic stem cell transplant patients.
- T2* MRI has been well established in the determination of organ iron burden in transfusion-associated hemochromatosis. Contrast use is not necessary for evaluation of iron burden. The following studies are medically necessary for evaluation of transfusion-associated hemochromatosis:
  - MRI Abdomen without contrast (CPT® 74181) for liver iron evaluation.
  - MRI Cardiac without contrast (CPT® 75557) for cardiac iron evaluation.
  - MRI Chest without contrast (CPT® 71550) can be approved as a single study to evaluate both heart and liver iron burden.
  - CPT® 74181 and CPT® 75557 can be approved alone, or together.
  - If requested, CPT® 71550 will evaluate both heart and liver and should not be approved with any other codes.
- Screening MRI is medically necessary every 12 months for chronically transfused individuals at risk of hemochromatosis.
- Imaging is medically necessary every 3 months for treatment response in individuals receiving active treatment (chelation and/or phlebotomy).

Indeterminate Renal Lesion (PEDAB-19)

ABP.RL.0019.A

v2.0.2026

- Indeterminate renal lesion characterization imaging indications in pediatric individuals are very similar to those for adult individuals. See: **Indeterminate Renal Lesion (AB-35)** in the Abdomen Imaging Guidelines.
- Indeterminate renal lesion imaging indications in pediatric individuals are uncommon and are usually cysts or congenital anomalies.
- Pediatric-specific imaging considerations include the following:
  - Pediatric renal cysts have a lower risk of malignant progression than do renal cysts in adults.
  - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160) is medically necessary for individuals who have simple cysts but are symptomatic and surgical intervention is being considered.
  - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen without and with contrast (CPT® 74170) is medically necessary for pediatric individuals with complex renal cyst identified on ultrasound.
  - For individuals with congenital anomalies, nuclear medicine studies with diuretic renography (CPT® 78708 or CPT® 78709) are medically necessary to determine function and cystography to determine presence of associated reflux.
  - Individuals with solid renal masses, see: **Pediatric Renal Tumors (PEDONC-7)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
  - Individuals with renal tumor predisposition syndromes, see: **Other Renal Cell Cancer Predisposition Syndromes (PEDONC-2.17)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Hydronephrosis (PEDAB-20)

ABP.HN.0020.A
v2.0.2026

Hydronephrosis is a relatively common finding in pediatric individuals, with the following imaging considerations:

- Evaluation of antenatal hydronephrosis (AHN) with retroperitoneal ultrasound (CPT® 76771)
  - Postnatal ultrasound within 24 hours of life is medically necessary for males with distended bladder or infants with moderate/severe antenatal hydronephrosis diagnosed prenatally.
  - Postnatal ultrasound after seven days of life is medically necessary for infants with mild prenatal hydronephrosis.
  - A second postnatal ultrasound, even if initial is normal, at 4-6 weeks of age is medically necessary for all infants with antenatal hydronephrosis.
  - After this, infants with known hydronephrosis may be followed by ultrasound every 3-12 months until resolution of hydronephrosis.
    - This imaging represents a guideline-supported, scheduled follow-up imaging evaluation, as described in **Clinical Information (Preface-3.1)** in the Preface Imaging Guidelines.
- Hydronephrosis associated with urinary tract infection or vesicoureteral reflux, see: **Urinary Tract Infection (UTI) (PEDAB-5)** for imaging guidelines.
- In individuals with obstructive uropathy (including ureteropelvic junction obstruction (UPJO), ureterovesical junction obstruction (UVJO), and bladder outlet obstruction), retroperitoneal ultrasound (CPT® 76770) and diuretic renography (CPT® 78707, CPT® 78708, or CPT® 78709) are medically necessary for preoperative planning and postoperatively at 3 to 12 months.
  - If hydronephrosis has resolved on postoperative imaging then no further routine imaging is indicated.
- Magnetic resonance urography (MRU) (CPT® 74183 and CPT® 72197) is medically necessary in individuals with inconclusive ultrasound and diuretic renography.
- CT Abdomen with contrast (CPT® 74160) is medically necessary in individuals with inconclusive ultrasound and a suspected vascular cause of UPJO.

Polycystic Kidney Disease (PEDAB-21)

ABP.PK.0021.A

v2.0.2026

- Abdominal ultrasound (CPT® 76700) or retroperitoneal ultrasound (CPT® 76770) is medically necessary for clinical concern of polycystic kidney disease, or for screening individuals who are at risk for autosomal dominant polycystic kidney disease (ADPKD).
- There are no established MRI-based diagnostic criteria for ADPKD in children younger than 15 years of age.
- For older children and teens, imaging indications for MRI Abdomen without contrast (CPT® 74181) would be identical to those for adult individuals. See: **Polycystic Kidney Disease (AB-38.1)** in the Abdomen Imaging Guidelines.

Spleen (PEDAB-26)

ABP.SP.0026.A

v2.0.2026

- Spleen imaging indications in pediatric individuals are very similar to those for adult individuals. See: **Spleen (AB-34)** in the Abdomen Imaging Guidelines.
- Nuclear medicine spleen imaging (CPT® 78185) is medically necessary for the following indications when CT is unavailable:
  - Splenic trauma
  - Evaluation of splenic function
  - Suspected splenic mass, cyst, abscess, infarct, or metastasis
  - Radiation treatment planning
  - Asplenia
  - Suspected functional accessory spleen:
    - CPT® 78215 or CPT® 78216 instead of CPT® 78185 is medically necessary, if requested
- Pediatric-specific imaging considerations include the following:
  - MRI is preferred over CT when possible to reduce radiation exposure.

Intussusception (PEDAB-27)

ABP.IN.0027.A

v2.0.2026

- Intussusception, telescoping of one bowel loop into another, is a frequent cause of abdominal pain in young children. It may be associated with bloody stool.
  - Ultrasound (CPT® 76700 or CPT® 76705) is medically necessary as an initial study if there is a strong suspicion for intussusception.
  - CT Abdomen and/or Pelvis with contrast (CPT® 74160 or CPT® 74177) is medically necessary to help characterize or diagnose pathologic lead points identified on ultrasound.

Bowel Obstruction (PEDAB-28.1)

ABP.BO.0028.1.A
v2.0.2026

- Suspected high-grade obstruction
  - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary (preferred to avoid unnecessary radiation exposure).
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if MRI is not readily available.
- Suspected intermittent or low-grade small bowel obstruction.
  - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary (preferred to avoid unnecessary radiation exposure).
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if MRI is not readily available.
  - If the etiology or level of suspected intermittent or low-grade small bowel obstruction remains undetermined and additional imaging is needed after CT Abdomen and Pelvis, the following are medically necessary:
    - CT Enteroclysis (CPT® 74176 or 74177), or
    - CT Enterography (CPT® 74177), or
    - MR Enteroclysis (CPT® 74183 and CPT® 72197), or
    - MR Enterography (CPT® 74183 and CPT® 72197)
- Small bowel obstruction suspected to be secondary to Crohn's Disease

Left Lower Quadrant Pain (PEDAB-29)

ABP.LP.0029.A
v2.0.2026

Diverticulitis is the most common cause of left lower quadrant pain in adults but is extremely rare in children.

- CT Abdomen and Pelvis (CPT® 74177) with contrast is medically necessary if there are any red flag signs or symptoms (as listed in **General Guidelines (PEDAB-1.0)**)
- In the absence of red flags, advanced imaging is rarely helpful in the initial evaluation of these individuals. Consultation with a gastroenterologist can be helpful in determining the appropriate diagnostic pathway.
  - Pelvic ultrasound (CPT® 76856) is the medically necessary initial imaging study of choice for children for detecting gynecologic abnormalities that may cause left lower quadrant pain.
  - For male individuals or if ultrasound is inconclusive, advanced imaging may be appropriate for management as directed by gastroenterological evaluation or consultation.

Vomiting Infant, Malrotation, and Hypertrophic Pyloric Stenosis (PEDAB-33)

ABP.VI.0033.A

v2.0.2026

- Vomiting in infants is generally classified as either bilious (implying obstruction distal to the Sphincter of Oddi) or non-bilious.
- Bilious vomiting may be a true emergency, as some of the conditions causing this could result in compromise of blood supply to the intestines, a potentially life-threatening situation.
- Suspected malrotation is an indication for emergent imaging. If malrotation with mid-gut volvulus is suspected, Ultrasound abdomen, limited (CPT® 76705) is medically necessary.
- Hypertrophic Pyloric Stenosis is an idiopathic condition wherein the circular muscle controlling emptying of the stomach thickens causing a relative obstruction of the gastric outlet. The condition can occur at any age (including occasionally in adults), but the typical child is male, aged 2 to 6 weeks. Projectile non-bilious vomiting is the most common presenting complaint, but the description of projectile vomiting is subjective. The differential diagnosis for non-bilious vomiting includes common conditions such as viral gastroenteritis and gastro-esophageal reflux.
  - US Abdomen, limited (CPT® 76705) is medically necessary for infants with persistent projectile non-bilious vomiting. If initial studies are not diagnostic, repeat studies are medically necessary (as frequently as daily) until the vomiting resolves or the diagnosis is made.

Acute Pancreatitis (PEDAB-34.1)

ABP.PX.0034.1.A
v2.0.2026

- The presence of any red flag findings per **General Guidelines (PEDAB-1.0)** precludes adjudication based on any other criteria.
  - If red flag is present (as per **General Guidelines (PEDAB-1.0)**), then CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen with contrast (CPT® 74160), or MRI/MRCP (CPT® 74183 or CPT® 74181) is medically necessary.
- Initial imaging
  - US Abdomen (CPT® 76700 or CPT® 76705) is medically necessary
  - If ultrasound performed and is nondiagnostic due to technical limitation (obesity, overlying gas, etc.), or if ultrasound is negative and there is continued clinical suspicion of acute pancreatitis, MRI/MRCP (CPT® 74183 or CPT® 74181) is medically necessary.
    - CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen with contrast (CPT® 74160) is medically necessary if MRI/MRCP cannot be performed.
  - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for management of acute pancreatitis in the following situations:
    - Evaluation of known or suspected complications of acute pancreatitis
    - To characterize degree of organization of collections before intervention
- Abdominal US (CPT® 76700 or CPT® 76705) is medically necessary to follow known fluid collections for resolution or progression.
- Acute Recurrent Pancreatitis (ARP)
  - MRI/MRCP (CPT® 74183 or CPT® 74181) is medically necessary for the following:
    - To identify structural or obstructive causes
    - To assess for progression to chronic pancreatitis
  - In a child who requires sedation for imaging, it is reasonable to alternate MRI/MRCP with Abdominal US (CPT® 76700 or CPT® 76705) or CT Abdomen with contrast (CPT® 74160) for serial monitoring of acute recurrent pancreatitis as recommended by or in consultation with a gastroenterologist or pancreatic specialist.

Background and Supporting Information

- The role of imaging is to identify findings at diagnosis, assess for local complications, identify potential etiologies, monitor evolution of local complications, plan and guide interventions.

Chronic Pancreatitis (PEDAB-34.2)

ABP.PX.0034.2.A

v2.0.2026

- The role of imaging is to contribute to or establish initial diagnosis, stage/monitor disease, assess for superimposed acute pancreatitis, identify potential etiologies of chronic pancreatitis, characterize secretory function, and/or plan for surgical intervention.
- If chronic pancreatitis is suspected, the following are medically necessary:
  - MRI Abdomen without and with contrast (CPT® 74183)
    - CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen with contrast (CPT® 74160) if MRI cannot be performed
- To evaluate suspected or known episode of acute pancreatitis in a child with chronic pancreatitis, the following is medically necessary:
  - Abdominal US (CPT® 76700 or CPT® 76705)
  - CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen with contrast (CPT® 74160) or MRI/MRCP (CPT® 74183 or CPT® 74181) are medically necessary in the following situations:
    - If ultrasound is negative and imaging diagnosis of acute pancreatitis is needed
    - If planning endoscopic or surgical interventions

General Guidelines (PEDCH-1.0)

CHP.GG.0001.0.A

v2.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms, including a detailed history, physical examination, and appropriate laboratory, and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MRI, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the chest is not supported. Advanced imaging of the chest is only supported in individuals who have documented active clinical signs or symptoms of disease involving the chest.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the chest are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Pediatric Chest Imaging Age Considerations (PEDCH-1.1)

CHP.GG.0001.1.A

v2.0.2026

- Many conditions affecting the chest in the pediatric population have different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals who are 18 years old or younger should be imaged according to the Pediatric Chest Imaging Guidelines if discussed. Any conditions not specifically discussed in the Pediatric Chest Imaging Guidelines should be imaged according to the General Chest Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Chest Imaging Guidelines, except where directed otherwise by a specific guideline section.

Pediatric Chest Imaging Modality General Considerations (PEDCH-1.3)

CHP.GG.0001.3.A
v2.0.2026

- MRI
  - MRI Chest is generally performed without and with contrast (CPT® 71552) unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, anesthesia is usually medically necessary for almost all infants (except neonate) and young individuals (age <7 years), as well as older individuals with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast is medically necessary if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
  - If multiple body areas are supported by the guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently.
  - The presence of surgical hardware or implanted devices may preclude MRI.
  - The selection of best examination may require coordination between the provider and the imaging service.
- CT

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - CT Chest is generally performed either with contrast (CPT® 71260) or without contrast (CPT® 71250).
    - There are no generally accepted pediatric indications for CT Chest without and with contrast (CPT® 71270).
  - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
  - The selection of best examination may require coordination between the provider and the imaging service.
- Ultrasound
  - Ultrasound Chest (CPT® 76604) or Axilla (CPT® 76882) is medically necessary as an initial study for evaluating adenopathy, palpable chest wall lesions, pleural effusion or thickening, patency of thoracic vasculature, and diaphragm motion abnormalities.
  - For those individuals who do require advanced imaging, ultrasound can be very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the individual.
- Nuclear Medicine
  - Nuclear medicine studies other than PET/CT are rarely used in evaluation of the pediatric chest.
  - Pulmonary Ventilation-Perfusion Imaging (CPT® 78582) has been replaced by CTA Chest (CPT® 71275) or CT Chest with contrast (CPT® 71260), but is medically necessary for evaluation of suspected pulmonary embolism if CT is unavailable.
    - See **Pulmonary Embolism (PE) (CH-25.1)** in the Chest Imaging Guidelines.
  - Pulmonary Perfusion Imaging (CPT® 78580) is not medically necessary in lieu of CPT® 78582 for initial evaluation of suspected pulmonary embolism, but is medically necessary for follow-up of an equivocal or positive ventilation-perfusion lung scan (CPT® 78582) to evaluate for interval change.
  - Pulmonary Ventilation Imaging (CPT® 78579) is not medically necessary in lieu of CPT® 78582 for evaluation of suspected pulmonary embolism, but is medically necessary for additional evaluation of an abnormal perfusion-only scan (CPT® 78580).
  - Pulmonary split crystal function study (CPT® 78597 or CPT® 78598), also known as Quantitative Differential Pulmonary Perfusion, is medically necessary for preoperative planning of segmental, lobar, or lung resection.
  - Quantitative Differential Pulmonary Perfusion Lung Scan (CPT® 78597 or CPT® 78598), can be performed post-lung transplant to detect regional perfusion abnormalities.
  - Radiopharmaceutical nuclear medicine imaging of an inflammatory process (CPT® 78800, CPT® 78801, CPT® 78802, or CPT® 78803) is rarely performed, but is medically necessary for evaluation of sarcoidosis or toxicity from drug toxicity (cyclophosphamide, busulfan, bleomycin, amiodarone, or nitrofurantoin).

Lymphadenopathy (PEDCH-2.1)

CHP.LY.0002.1.A
v2.0.2026

- Axillary lymphadenopathy imaging indications in pediatric individuals are identical to those for adult individuals. See **Axillary Lymphadenopathy (and Mass) (CH-2.2)** in the Chest Imaging Guidelines.
- Supraclavicular adenopathy in pediatric individuals is almost always pathologic, and advanced imaging is medically necessary prior to excisional biopsy. Fine-needle aspiration, while common in adults prior to advanced imaging, is not medically necessary for evaluating lymphadenopathy in pediatric individuals. ANY combination of the following studies are medically necessary for evaluation of supraclavicular adenopathy:
  - CT Chest with contrast (CPT® 71260)
  - MRI Chest without and with contrast (CPT® 71552)
  - Ultrasound Chest (CPT® 76604)
- If malignancy is suspected, refer to the condition specific imaging guidelines as below:
  - Lymphoma: **Pediatric Lymphomas (PEDONC-5)** in the Pediatric Oncology Imaging Guidelines.
  - Soft tissue sarcoma: **Pediatric Soft Tissue Sarcomas (PEDONC-8)** in the Pediatric Oncology Imaging Guidelines.
  - Neuroblastoma: **Neuroblastoma (PEDONC-6)** in the Pediatric Oncology Imaging Guidelines.

Evidence Discussion

In pediatric patients, supraclavicular lymphadenopathy is considered highly suspicious for malignancy and warrants prompt imaging evaluation. Unlike in adults, fine-needle aspiration is not routinely medically necessary prior to imaging in children. Ultrasound (US) remains a first-line modality due to its safety profile, absence of ionizing radiation, and ability to provide real-time soft tissue characterization. US is particularly useful in differentiating cystic from solid lesions and guiding further imaging or biopsy decisions.[1]

For axillary lymphadenopathy, pediatric imaging guidelines mirror those of adults, with US being the preferred initial modality. US is non-invasive, widely available, and effective in identifying reactive versus suspicious lymph nodes. It also facilitates image-guided biopsy when needed. CT Chest is generally not medically necessary unless there is a high suspicion of systemic disease or malignancy.[1]

Mediastinal Mass (PEDCH-3.1)

CHP.MM.0003.1.A

v2.0.2026

- The causes of mediastinal masses in pediatric individuals are generally different than those in adults, and therefore, imaging considerations are different. Up to half of all pediatric mediastinal masses are malignant.
- Chest x-ray is medically necessary as an initial study for all individuals with suspected mediastinal mass.
- CT Chest with contrast (CPT® 71260) is medically necessary for any mediastinal mass identified on chest x-ray.
  - Masses can be very large and anterior masses frequently cause compression of the trachea and/or mediastinal blood vessels.
- MRI Chest without and with contrast (CPT® 71552) is medically necessary to evaluate any of the following findings:
  - a posterior (paravertebral) mediastinal mass on CT Chest that invades the spinal canal
  - CT findings that are inconclusive regarding specific anatomy
  - Large anterior mediastinal masses only when anesthesia is not used to complete the study.
- PET/CT (CPT® 78815) is medically necessary prior to biopsy in pediatric individuals if lymphoma is known or strongly suspected or there is evidence of tracheal compression on CT imaging. See **Pediatric Lymphoma (PEDONC-5)** in the Pediatric Oncology Imaging Guidelines.
- MIBG (CPT® 78800, CPT® 78802, CPT® 78803, or CPT® 78804) is medically necessary prior to biopsy in pediatric individuals if neuroblastoma is known or strongly suspected. See **Neuroblastoma (PEDONC-6)** in the Pediatric Oncology Imaging Guidelines.
- Ultrasound chest (CPT® 76604) is medically necessary in individuals younger than 5 years old to distinguish prominent but otherwise normal thymus from true mediastinal mass.
- A single repeat CT Chest with contrast (CPT® 71260) is medically necessary to confirm stability and avoid biopsy when NONE of the following features are present:
  - anterior mediastinal mass
  - enlarged lymph nodes anywhere in the imaging field
  - lymphopenia
  - pleural effusion

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Evidence Discussion

In pediatric populations, mediastinal masses require careful imaging evaluation due to the high likelihood of malignancy and the unique anatomical and physiological considerations in children. Chest radiography is considered the initial imaging modality of choice for suspected mediastinal masses, as it is widely available, low-cost, and effective in detecting large masses.[6]

When a mediastinal mass is identified on chest x-ray, cross-sectional imaging with CT Chest with contrast or MRI Chest with and without contrast is usually medically necessary. CT provides excellent anatomical detail and is particularly useful for assessing mass effect on adjacent structures, while MRI is preferred in cases where radiation exposure is a concern or when further soft tissue characterization is needed. MRI is especially valuable in evaluating posterior mediastinal masses or when CT findings are inconclusive.[6]

PET/CT is not routinely medically necessary for initial evaluation but may be considered in specific oncologic contexts such as suspected neuroblastoma.[6] Ultrasound is generally not medically necessary for mediastinal mass evaluation in older children but may be useful in children under five years of age to differentiate a prominent thymus from a true mass.[3]

Hemoptysis – Imaging (PEDCH-4.1)

CHP.BL.0004.1.A
v2.0.2026

- True hemoptysis is rare in pediatric individuals. A detailed history, physical examination, and appropriate laboratory studies should be performed prior to considering advanced imaging.
  - Aspirated blood from epistaxis or emesis frequently presents as hemoptysis, and history and physical examination will aid in this assessment.
- Chest x-ray is medically necessary as an initial study for stable individuals.
  - Advanced imaging is not medically necessary to evaluate individuals with epistaxis when there is a normal chest radiograph and no personal or family history of underlying lung disease or bleeding disorder.
  - CT Chest with contrast (CPT® 71260) or CTA Chest (CPT® 71275) is medically necessary for all other pediatric individuals with true hemoptysis.
    - CT Chest without contrast (CPT® 71250) is medically necessary for individuals with a documented allergy to CT contrast or significant renal dysfunction.
- MRI is not medically necessary in the evaluation of pediatric hemoptysis.

Evidence Discussion

Hemoptysis in pediatric populations is rare but can be life-threatening, necessitating a structured diagnostic approach. The most common causes include lower respiratory tract infections, bronchiectasis, foreign body aspiration, and congenital heart or vascular anomalies.[2,3] A detailed clinical history and physical examination are essential to detect true hemoptysis from other causes of bleeding, such as epistaxis or gastrointestinal sources.[2]

Chest radiography is the recommended initial imaging modality for stable pediatric patients presenting with hemoptysis. It is widely available, low-cost, and can identify parenchymal abnormalities or foreign bodies.[2,3] If the chest x-ray is normal and there is no history of lung disease or bleeding disorder, advanced imaging may not be medically necessary. However, in cases of true hemoptysis with abnormal radiographic findings or persistent symptoms, CT Chest with contrast or CTA Chest is medically necessary to localize the bleeding source and evaluate for vascular anomalies or infections.[1,2] MRI is not routinely medically necessary in the evaluation of pediatric hemoptysis.[2]

Cystic Fibrosis (PEDCH-5.1)

CHP.CF.0005.1.A
v2.0.2026

- Chest x-ray is medically necessary for initial evaluation of acute clinical symptoms in individuals with cystic fibrosis.
- CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is medically necessary in the setting of any of the following (chest x-ray not required):
  - hemoptysis
  - pneumonia worsening despite antibiotic therapy
  - pleural effusion or empyema
  - suspected fungal pneumonia
  - monitoring treatment changes on bronchiectasis
  - expiratory CT for evaluating small airways disease
  - pre- and post-lung transplant evaluation
  - uncooperative individual
- Low dose CT Chest without contrast (CPT® 71250) is medically necessary **every 2 years** for monitoring of bronchiectasis and small airways disease.
- Cystic fibrosis-associated liver disease develops in 5-10% of individuals with cystic fibrosis. Advanced imaging may be medically necessary if concerned for liver disease. See **Liver Disease (PEDAB-16)** in the Pediatric Abdomen Imaging Guidelines.

Evidence Discussion

Chest imaging plays a critical role in the diagnosis and longitudinal management of pediatric patients with cystic fibrosis (CF). Chest x-ray remains the initial imaging modality of choice for evaluating acute respiratory symptoms due to its accessibility, low cost, and ability to detect complications such as pneumonia, pleural effusion, or bronchiectasis.[1]

CT Chest without contrast is medically necessary in specific clinical scenarios.[3,5] CT imaging provides superior anatomical detail and is particularly valuable for assessing bronchiectasis and small airways disease. Low-dose CT protocols are recommended every two years for monitoring disease progression and treatment response.[2,6]

MRI is not routinely used for pulmonary imaging in CF but may be considered in research settings or when radiation exposure is a concern.[4]

Bronchiolitis (PEDCH-6.1)

CHP.BR.0006.1.A
v2.0.2026

Bronchiolitis is a self-limiting viral infection causing inflammation of the small airways, most common in infants under 12 months of age.

- Chest x-ray or chest ultrasound (CPT® 76604) is medically necessary when there is a clinical suspicion of pneumonia or other complications.
- Advanced imaging is not medically necessary for routine evaluation or monitoring of bronchiolitis.
- CT Chest with contrast (CPT® 71260) is medically necessary for the following:
  - pleural effusion or empyema on relevant chest x-ray or chest ultrasound (CPT® 76604)
  - immunocompromised individual with acute pulmonary symptoms
  - abnormality on relevant chest x-ray suggesting condition other than bronchiolitis

Evidence Discussion

Bronchiolitis is a common viral lower respiratory tract infection in infants, particularly under 12 months of age. It is typically self-limiting and managed supportively. Imaging is not routinely medically necessary for diagnosis or monitoring, as clinical evaluation is usually sufficient.[1]

Chest x-ray or chest ultrasound is medically necessary only when there is a clinical suspicion of complications such as pneumonia, pleural effusion, or when the presentation is atypical.[3,6] Lung ultrasound has shown promise as a radiation-free alternative to chest x-ray in evaluating bronchiolitis and its complications, with studies demonstrating good diagnostic accuracy.[4,5]

Advanced imaging such as CT Chest is not medically necessary in routine bronchiolitis management. However, it may be necessary in specific cases such as immunocompromised patients with acute pulmonary symptoms, or when chest x-ray reveals abnormalities suggesting conditions other than bronchiolitis.[6]

Pneumonia (PEDCH-7.1)

CHP.PN.0007.1.A

v2.0.2026

- Pneumonia imaging indications in pediatric individuals are very similar to those for adult individuals. See **Pneumonia (CH-13.1)** in the Chest Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - Chest x-ray and/or Ultrasound chest (CPT® 76604) is medically necessary when the individual's condition does not respond to standard therapy.
  - CT Chest with contrast (CPT® 71260) is medically necessary for:
    - immunocompromised individuals with acute pulmonary symptoms
    - diagnosis of an abscess
    - necrotizing pneumonia cannot be confirmed
    - recurring pneumonia
    - acute complications
  - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is medically necessary for individuals with recurrent lower respiratory tract infections.
  - Ultrasound chest (CPT® 76604) is medically necessary as an alternative for evaluation of complicated or recurrent childhood pneumonia.

Evidence Discussion

Pneumonia remains a leading cause of morbidity in pediatric populations, and imaging plays a critical role in the diagnosis, management, and evaluation of complications. Chest x-ray is the first line imaging modality for children who do not respond to standard therapy or present with atypical symptoms.[1,6]

Ultrasound of the chest is increasingly recognized as a valuable alternative to chest radiography, particularly for evaluating complicated or recurrent pneumonia. It is radiation-free, portable, and has demonstrated high diagnostic accuracy in multiple studies.[3,7,18]

CT Chest is reserved for specific clinical scenarios, including immunocompromised children with acute pulmonary symptoms, suspected abscess or necrotizing pneumonia, recurrent lower respiratory tract infections, or acute complications.[2,6] CT provides detailed anatomical information and is particularly useful when other imaging modalities are inconclusive. MRI is not routinely used for pneumonia imaging in children due to limited availability and longer acquisition times.[14]

Coronavirus Disease 2019 (COVID-19) (PEDCH-7.2)

CHP.PN.0007.2.A

v2.0.2026

- Pediatric imaging for COVID-19 positive individuals are similar to those for adult individuals. See **Coronavirus Disease 2019 (COVID-19) (CH-13.2)** in the Chest Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - chest x-ray is the initial imaging test for all pediatric individuals
  - for concerns involving **Multisystem Inflammatory Syndrome in Children (MIS-C)** see **(PEDCD-12)**

Evidence Discussion

In pediatric populations, chest imaging is not recommended as a screening tool for COVID-19 in asymptomatic individuals or those with mild symptoms unless they are at risk for disease progression.[19,20] Viral testing remains the gold standard for diagnosis, and imaging should not replace laboratory confirmation.[19]

Chest x-ray is the initial imaging modality of choice in children with suspected or confirmed COVID-19 who present with moderate to severe symptoms or worsening respiratory status.[8, 20] CT is not routinely medically necessary but may be considered in cases with clinical deterioration, suspected complications, or when alternative diagnoses are being considered.[8,10]

Lung ultrasound has emerged as a useful adjunct in pediatric COVID-19 imaging, particularly in emergency and critical care settings. It offers a radiation-free alternative that can detect pulmonary involvement and guide management decisions.[9,11]

Solitary Pulmonary Nodule (PEDCH-8.1)

CHP.PM.0008.1.A
v2.0.2026

The Fleischner Society guidelines for solitary pulmonary nodule management do not apply to pediatric individuals. An incidental solitary pulmonary nodule in a individual representing a primary lung carcinoma has never been reported in the literature. Similarly, an extrathoracic malignancy presenting with an incidental solitary pulmonary nodule in an otherwise healthy individual is very rare.

- CT Chest with contrast (CPT® 71260) is medically necessary as a one-time evaluation of a pulmonary nodule incidentally discovered on other imaging.
- Follow-up imaging of an incidental solitary pulmonary nodule in an asymptomatic healthy individual is **not** medically necessary.
  - Follow-up imaging is medically necessary for the following:
    - immunocompromised individuals
    - malignancy (see below)
    - invasive infection
    - new or worsening pulmonary symptoms
- Individuals with a malignant solid tumor who have pulmonary nodules of any size should have imaging according to the guideline section for the specific cancer type. See **Pediatric Oncology Imaging Guidelines** for specific imaging indications.
- This guideline section does not apply to multiple pulmonary nodules, which are imaged according to the underlying disorder in pediatric individuals.

Evidence Discussion

Incidental pulmonary nodules in pediatric populations are rare and differ significantly from adult cases in terms of etiology and clinical significance. Unlike adults, the likelihood of a solitary nodule representing a primary lung carcinoma in a child is exceedingly low.[1,2]

CT Chest with contrast is medically necessary for a one-time evaluation of an incidental pulmonary nodule discovered on other imaging modalities.[5] Follow-up imaging is generally not medically necessary in asymptomatic, otherwise healthy children unless specific risk factors are present, such as immunocompromise, known malignancy, invasive infection, or new or worsening pulmonary symptoms.[5,8]

Studies emphasize the importance of distinguishing benign from potentially concerning nodules based on imaging characteristics and clinical context.[6,7] The Society for Pediatric Radiology and other expert panels recommend individualized management

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

strategies that avoid unnecessary radiation exposure while ensuring appropriate follow-up in high-risk cases.[2,6]

Background and Supporting Information

A **nodule** is any pulmonary or pleural lesion that is a discrete, spherical opacity 2-30 mm in diameter surrounded by normal lung tissue. A larger nodule is called a mass. Entities that are not nodules, and are considered benign, include non-spherical linear, sheet-like, two-dimensional or scarring opacities.

Positive PPD or Tuberculosis (PEDCH-9.1)

CHP.TB.0009.1.A
v2.0.2026

- Positive PPD and tuberculosis imaging indications in pediatric individuals are similar to those for adult individuals.
  - See **PPD or TB (Mycobacterium tuberculosis and Nontuberculous Mycobacterial Pulmonary Disease [NTM-PD]) (CH-14.1)** in the Chest Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - MRI Spine with and without contrast of the symptomatic spine level is medically necessary in individuals with concern for spinal involvement of tuberculosis.
  - MRI Chest with and without contrast (CPT® 71552) can be considered as a radiation-free alternative to chest CT in pediatric individuals.

Evidence Discussion

In pediatric populations, imaging plays a critical role in the diagnosis and management of tuberculosis (TB) and nontuberculosis mycobacterial pulmonary disease (NTM-PD). Chest radiography remains the first-line imaging modality for children with suspected TB, particularly in those with a positive tuberculin skin test or interferon-gamma release assay.[1,12]

While chest x-ray is useful for detecting active TB, its sensitivity is limited, especially in early or latent disease. In cases where chest x-ray findings are equivocal or when complications are suspected, CT Chest provides superior anatomical detail and is recommended.[9,10] CT is particularly valuable in those with persistent or recurrent symptoms.[8]

MRI is increasingly considered as a radiation-free alternative to CT in pediatric patients, especially for evaluating spinal involvement.[7,13] MRI Chest with and without contrast may be used in select cases where radiation exposure is a concern.

Background and Supporting Information

- Chest x-ray can be useful as the initial imaging study when TB is suspected.

Asthma (PEDCH-10.1)

CHP.AS.0010.1.A

v2.0.2026

- Chest x-ray and/or Ultrasound chest (CPT® 76604) is medically necessary to further evaluate respiratory distress when the individual's condition does not respond to standard therapy.
- Advanced imaging is not medically necessary for routine evaluation or monitoring of asthma.
- CT Chest without (CPT® 71250) or with (CPT® 71260) contrast is medically necessary for the following:
  - pleural effusion or empyema on relevant chest x-ray
  - immunocompromised individual with acute pulmonary symptoms
  - abnormality on relevant chest x-ray suggesting condition other than asthma, including suspected foreign body
  - asthma and poor response to bronchodilators or conventional inhaled corticosteroid therapy in whom associated conditions, such as allergic bronchopulmonary aspergillosis and eosinophilic pneumonia, can mimic asthma

Evidence Discussion

In pediatric asthma, imaging is not routinely medically necessary for diagnosis or monitoring, as clinical evaluation and response to therapy are typically sufficient. However, chest x-ray or ultrasound may be medically necessary when a child presents with respiratory distress that does not respond to standard therapy.[1,5]

Chest radiography is useful in identifying complications or alternative diagnoses such as pneumonia, pneumothorax, or foreign body aspiration.[3,4] Lung ultrasound has emerged as a promising tool for evaluating asthmatic pneumonia and other complications, offering a radiation-free alternative to chest x-ray.[6,8]

Advanced imaging such as CT Chest is not medically necessary for routine asthma evaluation but may be necessary in specific cases. These include poor response to bronchodilators or corticosteroids, suspected allergic bronchopulmonary aspergillosis, eosinophilic pneumonia, or when chest x-ray reveals abnormalities inconsistent with asthma.[5,7]

Health Equity Considerations

Asthma is the most common chronic disease among the pediatric population, caused by inflammation and muscle tightness around the airways. Symptoms include cough, wheeze, shortness of breath, and chest tightness. The disease can be mild or severe for intermittent periods of time. Asthma is treated by inhaled medications, delivering

Click Here to Return to the Main TOC

the medication directly to the lungs. The main types of inhalers are bronchodilators and steroids.[9]

Non-Hispanic Black children have a higher asthma prevalence than non-Hispanic White children as evidenced by increased emergency department visits, school absences, and long-term lung function impairment.[10] Factors related to this discrepancy include poor quality housing with issues including broken home infrastructure, as well as environmental exposure to cigarette smoke, mold, rodents, and insects.[11] Financial limitations are an additional determinant in accessing consistent healthcare and environmental modifications to manage asthma and to prevent emergency department visits and hospitalizations. Many of these factors related to the higher prevalence in non-Hispanic Black children are modifiable, such as the environment and lack of healthcare. To address inequities and modifiable factors, interventions are needed by key stakeholders on a community and individual level specific to impacted racial and ethnic groups.[12]

Pectus Deformities (PEDCH-11.1)

CHP.PD.0011.1.A

v2.0.2026

- CT Chest without contrast (CPT® 71250), MRI Chest with and without contrast (CPT® 71552), or MRI Chest without contrast (CPT® 71550) is medically necessary in individuals with a pectus deformity for any of the following:
  - preoperative planning
  - significant cardiac depression after chest x-ray and echocardiography (CPT® 93306)
  - evidence of pulmonary impingement after chest x-ray and pulmonary function tests (PFTs) if there is increasing shortness of breath
    - Note: It may not be possible to obtain PFTs in individuals younger than 9 years old.
  - evaluation of congenital heart disease or Marfan's syndrome when suspected

Evidence Discussion

Pectus deformities, including pectus excavatum and pectus carinatum, are common congenital chest wall abnormalities in pediatric populations. Imaging plays a critical role in the diagnosis, preoperative planning, and assessment of cardiopulmonary impact.[1,2]

In cases of significant cardiac depression or pulmonary impingement identified on chest x-ray and echocardiography or pulmonary function tests, advanced imaging with CT or MRI is medically necessary.[8] CT Chest is frequently used for preoperative planning due to its ability to provide detailed anatomical information and calculate indices such as the Haller Index. However, due to concerns about radiation exposure, MRI is increasingly favored in pediatric patients. MRI offers high-resolution imaging without radiation exposure and is particularly useful for evaluating cardiac compression and thoracic abnormalities.[4,7] MRI is also beneficial in assessing patients with congenital heart disease or syndromic conditions such as Marfan's syndrome.[3,5]

Vascular Ring (PEDCH-13.1)

CHP.VM.0013.1.A
v2.0.2026

- Chest x-ray is the recommended initial study in individuals with respiratory symptoms. A chest x-ray is not medically necessary for individuals diagnosed with a vascular ring on prenatal imaging studies.
- Barium esophagram is the recommended initial study in individuals with feeding difficulties.
- CT Chest with contrast (CPT® 71260), CTA Chest (CPT® 71275), MRA Chest (CPT® 71555), or MRI Chest without contrast (CPT® 71550) in individuals with known or suspected vascular ring is medically necessary after prenatal imaging studies, chest x-ray, or barium esophagram.
- Echocardiogram is medically necessary to rule out associated congenital heart disease.
  - CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325 are medically necessary for initial evaluation of individuals with vascular ring and no prior echocardiograms.

Evidence Discussion

Vascular rings are congenital anomalies of the aortic arch system that can encircle and compress the trachea and esophagus, leading to respiratory and feeding difficulties in pediatric patients. Early and accurate imaging is essential for diagnosis and surgical planning.[1,2]

Chest x-ray is typically the initial imaging modality in children presenting with respiratory symptoms, although it may be normal or nonspecific. Barium esophagram is recommended in children with feeding difficulties, as it can demonstrate esophageal compression suggestive of a vascular ring.[3,4]

Advanced imaging with CT Chest, CTA, MRA, or MRI Chest is medically necessary in children with known or suspected vascular rings following initial imaging. These modalities provide detailed anatomical information about the vascular structures and their relationship to the airway and esophagus. MRI is particularly advantageous in pediatric populations due to the absence of radiation.[5,8] Echocardiography is also essential to evaluate for associated congenital heart disease, which may coexist with vascular rings.[7]

Background and Supporting Information

Vascular rings generally present with either respiratory symptoms (stridor, wheezing, tachypnea, cough) or feeding difficulties (dysphagia, slow feeding, hyperextension of the

Pulmonary Sequestration (PEDCH-14.4)

CHP.CD.0014.4.A
v2.0.2026

- Pulmonary sequestration imaging indications in pediatric individuals are similar to those for adult individuals.
  - See **Pleural-Based Nodules and Other Abnormalities (CH-17.1)** in the Chest Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - CTA Chest (CPT® 71275) is the gold standard for diagnosing pulmonary lung abnormalities.
  - CT Chest with contrast (CPT® 71260) and MRI Chest without contrast (CPT® 71550) are alternative imaging modalities that can be used for diagnosis.

Evidence Discussion

Pulmonary sequestration is a rare congenital lung malformation characterized by nonfunctional lung tissue that lacks normal communication with the tracheobronchial tree and receives systemic arterial blood supply. In pediatric populations, early and accurate diagnosis is critical to avoid complications such as recurrent infections, respiratory distress, and misdiagnosis with other thoracic anomalies. CTA remains the gold standard for diagnosis, offering high-resolution visualization of abnormal vascular supply and lesion morphology, which is essential for surgical planning and clinical management.[12,18]

Studies have demonstrated that CT and CTA provide reliable identification of both intralobar and extralobar sequestration in children, with high sensitivity for detecting systemic arterial supply and venous drainage.[20] MRI may serve as a complementary modality, especially in cases where radiation exposure is a concern, although its diagnostic accuracy for vascular anomalies is generally lower than CTA.[21]

Imaging plays a critical role in differentiating pulmonary sequestration from other congenital lung malformations such as congenital pulmonary airway malformation and bronchogenic cysts.[13,14]

Click Here to Return to the Main TOC

Congenital Cystic Lung Diseases (PEDCH-14.1)

CHP.CD.0014.1.A
v2.0.2026

- This section includes common congenital cystic lung lesions such as:
  - bronchogenic cyst
  - congenital pulmonary airway malformation (congenital cystic adenomatoid malformation)
  - congenital lobar overinflation
- CT Chest with contrast (CPT® 71260) is medically necessary when a cystic lung lesion is suspected.
- MRI Chest with and without contrast (CPT® 71552) is medically necessary if CT is inconclusive or if requested for pre-operative planning.

Evidence Discussion

Congenital cystic lung diseases encompass a spectrum of developmental anomalies including bronchogenic cysts, congenital pulmonary airway malformations, and congenital lobar overinflation. Early and accurate imaging is essential for diagnosis, surgical planning, and monitoring.[1,2]

CT Chest is the primary imaging modality for evaluating suspected cystic lung lesions due to its high spatial resolution and ability to delineate lesion morphology and vascular anatomy.[11,18] MRI of the chest is medically necessary when CT findings are inconclusive or when detailed preoperative planning is required, particularly to avoid radiation in younger patients.[12,13] MRI is especially useful in evaluating complex lesions and their relationship to adjacent structures, and it provides superior soft tissue contrast without radiation exposure.[14,17]

Background and Supporting Information

- Cystic lung disease may be first identified on prenatal ultrasound, or discovered incidentally on chest x-ray.

Click Here to Return to the Main TOC

Pulmonary Arteriovenous Malformations (PEDCH-14.2)

CHP.CD.0014.2.A

v2.0.2026

- Pulmonary arteriovenous malformations (PAVMs) are vascular structures that most commonly result from abnormal communication between pulmonary arteries and pulmonary veins.
  - Chest x-ray is medically necessary as an initial imaging modality for individuals with known AVMs, or individuals presenting with hypoxemia and/or hemoptysis.
  - CTA or MRA is medically necessary in individuals with known AVM or abnormal chest x-ray suggesting AVM for treatment planning.

Evidence Discussion

Pulmonary arteriovenous malformations (PAVMs) are rare vascular anomalies that can lead to significant clinical symptoms such as hypoxemia and hemoptysis in pediatric populations. Early and accurate imaging is essential for diagnosis and treatment planning.[1,2]

Chest x-ray is the recommended initial imaging modality for children presenting with symptoms or known AVMs. While it may not detect small or atypical lesions, it provides a useful screening tool.[4]

CTA and MRA are medically necessary for further evaluation when chest x-ray findings are abnormal or when a known AVM requires treatment planning. These modalities offer detailed visualization of vascular anatomy. CTA is considered the gold standard for defining vascular structures, while MRA is preferred in younger patients to avoid radiation.[5,12]

Click Here to Return to the Main TOC

Congenital Diaphragmatic Hernia (PEDCH-14.3)

CHP.CD.0014.3.A

v2.0.2026

- Congenital diaphragmatic hernia (CDH) is a defect in the diaphragm which may allow the abdominal organs to enter the chest cavity, and may lead to compromised pulmonary function or may be associated with congenital heart disease.
  - Over 90% of the hernias occur in the posterolateral diaphragm (Bochdalek hernia) typically on the left side.
  - Most of the rest of the hernias are in the anteromedial diaphragm (Morgagni hernia).
- The vast majority of CDH are diagnosed prenatally (see **Fetal MRI [PV-15.1]**) in the Pelvis Imaging Guidelines), or as an inpatient shortly after delivery.
- If there is clinical concern for CDH, chest x-ray and/or US Chest (CPT® 76604) is medically necessary as the initial imaging study.
- CT Chest with contrast (CPT® 71260) or MRI Chest with and without contrast (CPT® 71552) is medically necessary when chest x-ray and/or US are inconclusive, or if requested for treatment planning.

Evidence Discussion

Congenital diaphragmatic hernia (CDH) is a developmental defect of the diaphragm that allows abdominal organs to herniate into the thoracic cavity, potentially impairing lung development and function. Most cases are diagnosed prenatally or shortly after birth, but imaging remains essential for diagnosis and treatment planning.[1,7]

Chest x-ray and ultrasound are the recommended initial imaging modalities when CDH is suspected postnatally. These modalities are effective in identifying herniated abdominal contents within the thoracic cavity and assessing lung volume.[8,9]

When initial imaging is inconclusive or further anatomical detail is required for surgical planning, CT chest or MRI chest is medically necessary. CT provides excellent spatial resolution, while MRI offers a radiation-free alternative, particularly beneficial in neonates and infants.[10,12]

Advanced imaging also aids in identifying associated anomalies such as congenital heart disease or pulmonary hypoplasia. Structured imaging protocols and multidisciplinary collaboration are essential for optimal diagnosis and management of CDH.[11,18]

General Guidelines (PEDHD-1.0)

HDP.GG.0001.0.A

v2.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination with a thorough neurologic examination since the onset or change in signs and/or symptoms, appropriate laboratory studies and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MR, Nuclear Medicine), unless the individual is undergoing a guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail, or messaging) since the onset or change in signs and/or symptoms can serve as a pertinent clinical evaluation.
  - A detailed neurological exam is required prior to advanced imaging except in the following scenarios:
    - Individual is undergoing a guideline-supported scheduled follow-up imaging evaluation
    - Tinnitus, TMJ, sinus or mastoid disease, ear pain, hearing loss, eye disease, papilledema, dental requests and epistaxis (a relevant physical exam is still required)
    - The request is from a neurologist, neurosurgeon, endocrinologist, otolaryngologist, or ophthalmologist who has evaluated the individual since onset of symptoms.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the head is not medically necessary. Advanced imaging of the head is only medically necessary in individuals who have documented active clinical signs or symptoms of disease involving the head.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the head are not medically necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

Health Equity Consideration

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence;

Pediatric Head Imaging Age Considerations (PEDHD-1.1)

HDP.GG.0001.1.A

v2.0.2026

- Many conditions affecting the head in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, minor differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals who are 18 years old or younger and any conditions not specifically discussed in the General Head Imaging Guidelines should be imaged according to the Pediatric Head Imaging Guidelines. Any conditions not specifically discussed in the Pediatric Head Imaging Guidelines should be imaged according to the General Head Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Head Imaging Guidelines, except where directed otherwise by a specific guideline section.

Pediatric Head Imaging Appropriate Clinical Evaluation (PEDHD-1.2)

HDP.GG.0001.2.A
v2.0.2026

Requests for Studies with Overlapping Fields

- There are many CPT® codes for imaging the head that have significantly overlapping fields. In the majority of cases where multiple head CPT® codes are requested, only one CPT® code is appropriate unless there is clear documentation of a need for the additional codes to cover all necessary body areas.
- See **General Guidelines - Anatomic Issues (HD-1.1)** in the Head Imaging Guidelines for the correct coding of these studies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pediatric Head Imaging Modality General Considerations (PEDHD-1.3)

HDP.GG.0001.3.A
v2.0.2026

- MRI
  - MRI is superior to CT imaging of the pediatric head unless otherwise stated in a specific guideline section.
  - Anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years) as well as older children with delays in development or maturity.
  - MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI/MRA of all necessary body areas, when multiple body areas are supported by the guidelines for the clinical condition being evaluated, should be obtained concurrently in the same anesthesia session.
    - MRI without and with contrast is medically necessary if requested to avoid repetitive anesthesia administration that would be needed to perform an MRI with contrast, if the initial study without contrast is inconclusive when:
      - intravenous access will already be present for anesthesia administration **AND**
      - there is no contraindication for using contrast.
  - For MRI spine imaging with contrast to be performed following a contrast-enhanced MRI Brain, see **CNS Tumors General Considerations (PEDONC-4.1)** in the Pediatric and Special Populations Oncology Guidelines.
- CT
  - CT is generally inferior to MRI for imaging of the pediatric head but has specific indications in which it is the preferred modality listed in specific sections of these guidelines.
    - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
  - CT Head without contrast (CPT® 70450) may be medically necessary for:
    - Mass effect
    - Blood/blood products
    - Urgent/emergent settings due to availability and speed of CT
    - Trauma
    - Recent hemorrhage, whether traumatic or spontaneous
    - Bony structures of the head evaluations including dystrophic calcifications
    - Hydrocephalus evaluation and follow-up

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Some centers use limited non-contrast “fast or rapid MRI” (CPT® 70551) to minimize radiation exposure in children - these requests are appropriate.
  - Prior to lumbar puncture in individuals with cranial complaints
  - Scenarios in which MRI is contraindicated (e.g., pacemakers, ICDs, cochlear implants, aneurysm clips, orbital metallic fragments, etc.)
  - Concern for calcifications
- CT and MR Angiography (CTA and MRA) Head and Neck
  - Contrast level
    - MRA Head may be performed without contrast (CPT® 70544), with contrast (CPT® 70545), or without and with contrast (CPT® 70546).
    - CTA Head may be performed/done without and with contrast (CPT® 70496).
    - MRA Neck may be done either without contrast (CPT® 70547), with contrast (CPT® 70548), or without and with contrast (CPT® 70549), depending on facility preference and protocols and type of scanner.
    - CTA Neck is done without and with contrast (CPT® 70498).
    - CTA Head and Neck without and with contrast (CPT® 70471). This code is must be substituted when both CTA Head and Neck may be performed together during the same session.
  - Indications for CTA and MRA Head and Neck vessels include, but are not limited to the following:
    - Pulsatile tinnitus
    - Hemifacial spasm, if consideration for surgical decompression
    - Evaluation of stroke or TIA (See **Pediatric Stroke Initial Imaging (PEDHD-12.2)**, **Pediatric Stroke Subsequent Imaging (PEDHD-12.3)**, **Moyamoya Disease (PEDHD-12.4)**, **Sickle Cell Disease (PEDHD-12.5),** and **CNS Vasculitis (PEDHD-12.6)** including collateral assessment)
    - Follow-up of known cerebral artery stenosis
    - Trigeminal neuralgia that has failed medical therapy
    - Cerebral sinus thrombosis suspected with increased intracranial pressure (refractory headaches, papilledema, diagnosis of pseudotumor cerebri)
    - Aneurysm suspected with acute "thunderclap" headache syndrome and appropriate screening or evaluation of known subarachnoid hemorrhage and pseudoaneurysms (may be appropriate to limit CTA to include only the head to avoid unnecessary radiation to the individual) (See **Pediatric Intracranial Aneurysms (PEDHD-10.1)**)
    - Noninflammatory vasculopathy, including radiation vasculopathy (See **Long Term Pediatric Cancer Survivors (PEDONC-19)** in the Pediatric and Special Populations Oncology Imaging Guidelines)
    - Traumatic vascular injuries

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - Vascular malformations, vascular anatomic variants, and fistulas (See **Pediatric Intracranial Arteriovenous Malformations (AVM) (PEDHD-10.2)**)
        - Arterial, including carotid dissections
        - Tumors of vascular origin or involving vascular structures
        - Surgical and radiation therapy localization, planning, and neuronavigation
        - Evaluation for vascular intervention and follow-up including post-surgical/post-treatment vascular complications
        - Intra-cranial pre-operative planning if there is concern of possible vascular involvement or risk for vascular complication from procedure
        - Vasculitis and collagen vascular disease (See **CNS Vasculitis (PEDHD-12.6)**)
        - Sickle cell disease (See **Sickle Cell Disease (PEDHD-12.5)**)
        - Moyamoya disease (See **Moyamoya Disease (PEDHD-12.4)**)
        - Evaluation of posterior circulation disease requires both neck and head MRA/CTA to visualize the entire vertebral-basilar system
    - For follow-up of aneurysm clipping or coiling procedures, see **Intracranial Aneurysms (HD-12.1)** in the Head Imaging Guidelines.
- CT and MR Venography (CTV and MRV)
    - CTV and MRV are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography).
    - If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code should be used to report both procedures.
    - MRA without and with contrast with venous sinus thrombosis to differentiate total from subtotal occlusion
- Ultrasound
    - Cranial ultrasound (CPT® 76506) is a non-invasive means of evaluating for intracranial abnormalities in infants with an open anterior fontanelle.
    - Transcranial Doppler ultrasonography has some utility in select populations of older children with known or suspected intracranial vascular disease.
- Nuclear Medicine
    - Nuclear medicine studies other than metabolic PET imaging on the pediatric brain or head are rarely performed in an elective outpatient setting, but the following studies are medically necessary for the following indications:
        - Brain Scintigraphy with or without vascular flow (any one of CPT® codes: CPT® 78600, CPT® 78601, CPT® 78605, or CPT® 78606)
            - Establish brain death
        - Radiopharmaceutical Localization Imaging SPECT (CPT® 78803)
            - Immunocompromised individuals with mass lesion detected on CT or MRI for differentiation between lymphoma and infection

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - Radiopharmaceutical Localization Imaging SPECT (CPT® 78803) with vasodilating agent acetazolamide (Diamox) challenge when surgery or other vascular intervention is being considered (i.e., Moyamoya)
    - Brain Imaging Vascular Flow (CPT® 78610)
        - Cerebral ischemia
        - Establish brain death (rarely done in outpatient setting)
    - CSF Leakage Detection (CPT® 78650)
        - Evaluation of CSF rhinorrhea or otorrhea, or refractory post-lumbar puncture headache
    - Radiopharmaceutical Dacryocystography (CPT® 78660)
        - Suspected obstruction of nasolacrimal duct due to excessive tearing
- 3D Rendering
    - CPT® 76377 (3D rendering requiring image post-processing on an independent workstation) or CPT® 76376 (3D rendering not requiring image post-processing on an independent workstation) is medically necessary in the following clinical scenarios:
        - Bony conditions:
            - Evaluation of congenital skull abnormalities in newborns, infants, and toddlers (usually for pre-operative planning)
            - Complex joint fractures or pelvis fractures
            - Spine fractures (usually for pre-operative planning)
            - Complex facial fractures
        - Pre-operative planning for other complex surgical cases
        - Cerebral angiography
    - 3D Rendering (CPT® 76377 or CPT® 76376) is medically necessary for surgical planning and surgical follow-up after craniotomy when ordered by a surgical specialist.
    - 3D Rendering indications in pediatric head imaging are identical to those in the general imaging guidelines. See **3D Rendering (Preface-4.1)** in the Preface Imaging Guidelines.
- CT or MRI Perfusion (See **CT or MRI Perfusion (HD-24.5)** in the Head Imaging Guidelines.)

Background and Supporting Information

- The guidelines listed in this section for certain specific indications are not intended to be all-inclusive. Clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.
- “The U.S. Food and Drug Administration (FDA) is warning that repeated or lengthy use of general anesthetic and sedation drugs during surgeries or procedures in children younger than 3 years or in pregnant women during their third trimester may

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

affect the development of children's brains. … Published studies in pregnant animals and young animals have shown the use of general anesthetic and sedation drugs for more than 3 hours caused widespread loss of nerve cells in the brain. …All the studies in children had limitations, and it is unclear whether any negative effects seen in children's learning or behavior were due to the drugs or to other factors, such as the underlying medical condition that led to the need for the surgery or procedure."

- Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
  - The FDA has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.

General Guidelines-Other Imaging Situations (PEDHD-1.4)

HDP.GG.0001.4.A

v2.0.2026

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) can be performed for nausea and vomiting which is persistent and unexplained and there is a negative GI evaluation.
- Screening for metallic fragments before MRI should be done initially with plain x-ray.
- Plain x-ray is generally sufficient to screen for aneurysm clips.
- For neurosarcoidosis, see **Autoimmune/Paraneoplastic Encephalitis & Neuroinflammatory Disorders (HD-14.3)**.

Background and Supporting Information

- The use of CT Orbital to rule out orbital metallic fragments prior to MRI is rarely necessary.
- Plain x-rays are generally sufficient; x-ray detects fragments of 0.12 mm or more, and CT detects those of 0.07 mm or more.

Magnetic Resonance Spectroscopy (MRS, CPT® 76390) (PEDHD-2.1)

HDP.SI.0002.1.A

v2.0.2026

- Magnetic Resonance Spectroscopy (MRS) involves the analysis of the levels of certain chemicals in pre-selected voxels (small regions) on an MRI scan done at the same time.
- Uses in pediatric neuro-oncology: See **Pediatric CNS Tumors (PEDONC-4)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- MRS is medically necessary in individuals with neonatal hypoxic ischemic encephalopathy to help estimate the age of the injury.
- Uses in Metabolic Disorders:
  - See **Neurometabolic and Neurogenetic Disorders (PEDHD-19.4)**.
- MRS is considered not medically necessary for all other pediatric indications at this time.

Proprietary Information of UnitedHealthcare.

Functional Magnetic Resonance Imaging (fMRI, CPT® 70554 and CPT® 70555) (PEDHD-2.2)

HDP.SI.0002.2.A

v2.0.2026

- fMRI is medically necessary to define eloquent areas of the brain as part of pre-operative planning for epilepsy surgery or removal of a mass lesion.
  - The documentation should be clear that brain surgery is planned.
  - Can be performed concurrently with MRI Brain (CPT® 70551 or CPT® 70553) and/or PET Brain Metabolic (CPT® 78608 or CPT® 78609).
- fMRI is considered not medically necessary for all other pediatric indications at this time.

Click Here to Return to the Main TOC

PET Brain Imaging (CPT® 78608) (PEDHD-2.3)

HDP.SI.0002.3.A
v2.0.2026

- Metabolic FDG PET (CPT® 78608)
  - For pre-operative planning for epilepsy surgery, see **Special Imaging Studies in Evaluation for Epilepsy Surgery (PEDHD-6.3)**.
  - For encephalitis including autoimmune encephalitis, see **Autoimmune/ Paraneoplastic Encephalitis & Neuroinflammatory Disorders (HD 14.3)**.
  - For uses in pediatric neuro-oncology, see **Pediatric CNS Tumors (PEDONC-4)**.
  - Metabolic FDG PET (CPT® 78608) is considered not medically necessary for all other pediatric indications at this time.
- For Metabolic PET/MRI, see **Special Imaging Studies in Evaluation for Epilepsy Surgery (PEDHD-6.3)**.

Background and Supporting Information

- FDG PET Brain is medically necessary to define active areas of the brain as part of pre-operative planning for epilepsy surgery.
- FDG PET Brain/MRI is generally not medically necessary for neurological conditions, except pre-operative planning for epilepsy surgery, due to lack of standardization in imaging technique and interpretation.

Pediatric Headache (PEDHD-3.1)

HDP.PH.0003.1.A

v2.0.2026

- A pertinent clinical evaluation including a detailed history and physical examination with a thorough neurologic examination, since the onset or change in signs and/or symptoms, and appropriate laboratory studies should be performed prior to considering advanced imaging.
- Advanced imaging is not medically necessary for pediatric individuals with headache in the absence of supported indications.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging Study
◦ Age less than or equal to 5 years ◦ Focal neurological complaints including acute hypertension or altered mental status ◦ Clumsiness (common description of gait or coordination problems in young children) ◦ Headaches awakening from sleep or always present in the morning ◦ Headaches associated with morning nausea/vomiting ◦ Seizures ◦ Progressive worsening in headache frequency and severity without period of temporary improvement ◦ Systemic symptoms such as persistent fever, weight loss, rash, or joint pain ◦ Immunocompromised individual ◦ Known history of cancer of any type ◦ Known autoimmune or rheumatologic disease ◦ Known genetic disorder with predisposition to intracranial mass lesions ◦ History of stable chronic headaches with recent significant change in frequency or severity ◦ Neurological signs and/or symptoms, including headache, after COVID-19 infection ◦ If a recent CT Head is inconclusive	◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553)
◦ Abnormality identified on MRI Brain without contrast (CPT® 70551)	◦ MRI Brain with contrast (CPT® 70552) **OR** ◦ MRI Brain without and with contrast (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indications	Medically Necessary Imaging Study
◦ Headache precipitated by coughing, sneezing, physical exertion, or Valsalva ◦ Thunderclap headache ◦ Individual with hypercoagulable state or bleeding disorder	◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553) **AND/OR** ◦ MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** ◦ CTA Head (CPT® 70496)
◦ Papilledema on physical exam ◦ Focal signs and/or symptoms of bruit, dissection, vertebrobasilar insufficiency, and/or positional changes	◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553) **AND/OR** ◦ MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** ◦ CTA Head (CPT® 70496) **OR** ◦ MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) For requests of MRA OR CTA AND MRV, see **Pediatric Head Imaging Modality General Considerations (PEDHD-1.3)**.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging Study
◦ Urgent/Emergent settings ◦ Sudden severe headache including thunderclap headache ◦ Acute setting of suspected intracranial infection prior to lumbar puncture (CT Head with contrast CPT® 70460 if intracranial spread of disease is suspected, to detect suppurative fluid collections) (See **General Guidelines-Other Imaging Situations (PEDHD-1.4)**) ◦ Concern for new hemorrhage, significant mass effect, or hydrocephalus and/or rapid clinical deterioration ◦ Recent head trauma ◦ Suspected skull or other bony involvement ◦ If MRI is contraindicated ◦ Ventriculoperitoneal shunt with suspected shunt malfunction. See **Macrocephaly, Microcephaly, and Hydrocephalus (PEDHD-7)** for additional imaging.	◦ CT Head without contrast (CPT® 70450) *CT Head permitted even with prior MRI Brain imaging.*

- If concern for CNS infection, see **CNS Infection (PEDHD-29)**.

Background and Supporting Information

- Headache is a very common complaint in school aged children and adolescents. Many of these children have a family history of one of the primary headache disorders, such as migraine or tension headache.
- CT Head poorly visualizes the posterior fossa in children and is generally insufficient to evaluate pediatric headaches in the absence of supported indications. CT is not supported in lieu of MRI solely to avoid sedation. See **Pediatric Head Imaging Modality General Considerations (PEDHD-1.3)**.

Head Trauma (PEDHD-4.1)

HDP.PS.0004.1.A
v2.0.2026

- In individuals with recent head trauma, a history focused on the incident and careful examination of the head, neck, and neurological function should be performed since the onset or change in signs and/or symptoms prior to considering advanced imaging.
- Advanced imaging is medically necessary for children with head trauma with ANY of the following red flags:
  - Loss of consciousness
  - Altered mental status or abnormal behavior
  - Known or suspected skull fracture
  - Glasgow Coma Score <15
  - Age younger than 2 years
  - Vomiting
  - Severe mechanism of injury, including, but not limited to:
    - Motor vehicle crash with patient ejection
    - Motor vehicle crash with death of another passenger
    - Motor vehicle crash with rollover
    - Pedestrian or bicyclist without helmet struck by a motorized vehicle
    - Head struck by a high-impact object
    - Falls of more than 1.5m (5 feet) for children aged 2 years and older and more than 0.9m (3 feet) for those younger than 2 years
  - Severe or worsening headache
  - Amnesia
  - Non-frontal scalp hematoma
- CT Head without contrast (CPT® 70450) is the primary advanced imaging study in individuals with acute head trauma.
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for the following:
  - Children with an abnormal neurological exam that is not explained by the CT findings
  - Subacute (8 days to one month after initial traumatic event) or chronic blunt head trauma with new or worsening neurological signs or cognitive symptoms
  - Children suspected of being the victims of physical abuse. See **Suspected Physical Child Abuse (PEDMS-7)** in the Pediatric Musculoskeletal Imaging Guidelines.
- For facial trauma, see **Facial Trauma (PEDHD 4.2)** in the Pediatric Head imaging Guidelines.

Sinus And Facial Imaging General Considerations (PEDHD-5.1)

HDP.AR.0005.1.A

v2.0.2026

- Acute sinusitis is a clinical diagnosis, and imaging is not medically necessary to establish a diagnosis. Acute bacterial sinusitis can be presumptively diagnosed in a child with acute upper respiratory infection (URI) symptoms and any of the following:
  - Persistent symptoms lasting >10 days without improvement.
  - Worsening symptoms after initial period of improvement.
  - Severe symptoms including purulent nasal discharge and fever >102.2°F for at least 3 consecutive days.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Imaging Indications in Sinusitis (PEDHD-5.2)

HDP.AR.0005.2.A

v2.0.2026

- Mild mucosal thickening in the paranasal sinuses or mastoids is an extremely common incidental finding noted on head imaging studies done for other indications. If there are no other abnormalities of facial structures noted, this finding is not an indication for advanced imaging of the sinuses or temporal bone.
- CT Maxillofacial without contrast (CPT® 70486) is medically necessary if ANY of the following is present:
  - No improvement after 10 days of appropriate antibiotic treatment (generally this will be amoxicillin/clavulanate, amoxicillin, cefdinir, cefuroxime, cefpodoxime, or ceftriaxone)
  - Recurrence of a treated infection within 8 weeks of effective treatment
  - Chronic sinusitis (persistent residual URI symptoms, including nasal obstruction, facial pressure/pain or cough for >90 days)
  - Known or suspected fungal sinusitis
    - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary if requested instead of CT Maxillofacial.
  - Pre-operative evaluation to assess surgical candidacy
- CT Maxillofacial with contrast (CPT® 70487) is medically necessary if ANY of the following is present:
  - Orbital or facial cellulitis
  - Proptosis
  - Abnormal visual examination
  - Ophthalmoplegia
  - Immunocompromised individual
  - Fungal or vascular lesions visualized in nasal cavity
- CT Head with contrast (CPT® 70460) **OR** MRI Brain without and with contrast (CPT® 70553) **OR** MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary if ANY of the following are present:
  - Focal neurologic findings
  - Altered mental status
  - Seizures
  - Concern for orbital complications
  - Concern for invasive fungal sinusitis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** CTA Head (CPT® 70496) is medically necessary with these findings as well if there is clinical concern for associated vascular complications including but not limited to mycotic aneurysm or venous sinus thrombosis.
- Repeat sinus imaging is generally not medically necessary for individuals who have responded satisfactorily to treatment but is medically necessary with clear documentation of the need for updated CT results to direct acute individual care decisions.

Proprietary Information of UnitedHealthcare.

Stereotactic CT Localization (CPT® 77011) (PEDHD-5.3)

HDP.AR.0005.3.A

v2.0.2026

- Stereotactic CT localization is frequently obtained prior to sinus surgery. The dataset is then loaded into the navigational workstation in the operating room for use during the surgical procedure. The information provides exact positioning of surgical instruments with regard to the individual's 3D CT images. In most cases, the pre-operative CT is a technical-only service that does not require interpretation by a radiologist.
- For treatment planning for sinus surgery CPT® 77011: A stereotactic CT localization scan is frequently obtained prior to sinus surgery. The dataset is then loaded into the navigational workstation in the operating room for use during the surgical procedure. The imaging facility should report CPT® 77011 when performing a scan not requiring interpretation by a radiologist.
- If a diagnostic scan is performed and interpreted by a radiologist, the appropriate diagnostic CT code (e.g., CPT® 70486) should be used.
- It is not appropriate to report both CPT® 70486 and CPT® 77011 for the same CT stereotactic localization imaging session.
- 3D Rendering (CPT® 76376 or CPT® 76377) should not be reported in conjunction with CPT® 77011 (or CPT® 70486 if used). The procedure inherently generates a 3D dataset.
- Such operative studies are medically necessary when ordered by the operating surgeon for this purpose.

Proprietary Information of UnitedHealthcare.

Requests for both Head and Sinus Imaging (PEDHD-5.4)

HDP.AR.0005.4.A
v2.0.2026

- CT Head does not visualize all of the sinuses.
- MRI Brain provides excellent visualization of the sinuses sufficient to recognize sinusitis, and addition of sinus CT for this purpose is unnecessary.
- In individuals being evaluated for potential sinus surgery, separate CT Sinus is often appropriate even after an MRI Brain in order to visualize obstructions to spontaneous mucus flow. See **Stereotactic CT Localization (CPT® 77011) (PEDHD-5.3)**.
- Separate head imaging is not medically necessary in individuals with a normal neurological examination who have headaches associated with sinus symptoms.
- CT or MRI Sinus is not medically necessary for the evaluation of headaches or neurological complaints without a more specific indication pointing to a sinus etiology.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Allergic Rhinitis (PEDHD-5.5)

HDP.AR.0005.5.A

v2.0.2026

- Advanced imaging is not medically necessary for diagnosis or management of individuals with uncomplicated allergic rhinitis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Other Indications for Sinus Imaging (PEDHD-5.6)

HDP.AR.0005.6.A
v2.0.2026

- See **Facial Trauma (PEDHD-4.2)** for imaging guidelines in trauma.
- CT Maxillofacial without contrast (CPT® 70486) - Congenital anomalies of facial structures.
- Cleft lip and palate can be associated with brain malformations and abnormal brain development.
  - MRI Brain (CPT® 70551) is medically necessary in cases of cleft lip and/or palate.
  - MRI Orbits/Face/Neck without contrast (CPT® 70540) or MRI Orbits/Face/Neck without and with contrast (CPT® 70543) is appropriate if requested by surgeon or any provider in consultation with the surgeon. See **Facial Anomalies (PEDHD-8.2)**.
- 3D CT reconstructed images (CPT® 76377 **OR** CPT® 76376) in conjunction with routine CT should be an integral part of the examination in evaluating craniofacial abnormalities.
- CT Maxillofacial without and with contrast (CPT® 70488) **OR** MRI Orbits/Face/Neck without and with contrast (CPT® 70543) - Tumors or other disorders of facial structures.
- Obstructive sleep apnea - See **Pediatric Sleep Disorders (PEDHD-24.1)** for imaging guidelines.
- See **Sinus and Facial Imaging (HD-29)** for conditions not addressed in **Sinus and Facial Imaging (PEDHD-5)**.

Epilepsy and Other Seizure Disorders (PEDHD-6.0)

HDP.EP.0006.0.A

v2.0.2026

- A pertinent evaluation including a detailed history, physical examination with a thorough neurologic examination, since the onset or change in signs and/or symptoms, and appropriate laboratory studies should be performed prior to considering the use of an advanced imaging (CT, MRI, Nuclear Medicine) procedure. An exception can be made if the individual is undergoing guideline-supported, scheduled follow-up imaging evaluation or request is from or in consultation with a neurologist or neurosurgeon who has seen the individual since onset of symptoms. This clinical evaluation should also include family history and (whenever possible) the accounts of eyewitnesses to the event(s).

Initial Imaging of Non-Febrile Seizures (PEDHD-6.1)

HDP.EP.0006.1.A

v2.0.2026

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for the following:
  - First-time seizure in child that has no known cause and is not associated with fever
  - Focal onset seizures
  - New onset primary generalized epilepsy (e.g., absence epilepsy or juvenile myoclonic epilepsy) in those who are neurologically abnormal (e.g., developmental delay)
  - Focal neurologic deficits
  - Inconclusive findings on recent cranial ultrasound or CT Head
    - If an individual meets criteria for MRI imaging for initial imaging of non-febrile seizure, MRI is medically necessary even with a recent negative CT.
  - Concern for a mass lesion or demyelinating disease
- CT Head without contrast (CPT® 70450) is medically necessary for the following (and does not preclude MRI imaging when requested):
  - First-time seizure in child associated with recent head trauma
  - Individual cannot safely undergo MRI (avoidance of sedation is not an indication) or in urgent situations
  - Concern for blood and/or calcifications
- Cranial ultrasound (CPT® 76506) for the following:
  - First-time seizure in child <30 days of age that has no known cause and is not associated with fever if the infant has an open fontanelle.
  - Cranial ultrasound is not required before MRI Brain for hypoxic ischemic encephalopathy (HIE) and/or congenital malformations.

Repeat imaging indications (PEDHD-6.2)

HDP.EP.0006.2.A

v2.0.2026

- Repeat MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for the following:
  - Need to perform MRI using Epilepsy Protocol (typically 3T magnet with thin section angled slices through hippocampus and temporal lobes, either without or without and with contrast)
  - New or worsening focal neurologic deficits
  - Drug-resistant epilepsy (DRE) (See **Background and Supporting Information** below.)
  - Change in seizure type
  - Repeat imaging for persistent seizures as requested by a specialist or any provider in consultation with a specialist
  - MRI Brain with contrast (CPT® 70552) **OR** MRI Brain without and with contrast (CPT® 70553) to clarify an abnormality on non-contrast MRI or if considering infection or inflammation

Background and Supporting Information

- DRE occurs when there is failure of 2 antiseizure medications (ASMs).
- DRE can also be referred to as "refractory", "intractable," and/or "pharmacoresistant" epilepsy.

Special Imaging Studies in Evaluation for Epilepsy Surgery (PEDHD-6.3)

HDP.EP.0006.3.A
v2.0.2026

- For individuals with a previous MRI Brain and documentation of intractable epilepsy for which surgical treatment or another interventional modality is under active consideration (see **Background and Supporting Information**), any or all of the following requests can be obtained concurrently and are medically necessary:
  - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast 3T/7T (CPT® 70553) **AND/OR**
  - Ictal SPECT (CPT® 78803 or CPT® 78830) **AND/OR**
  - Functional MRI (f-MRI) (CPT® 70555 or CPT® 70554) See **Functional MRI (fMRI) (HD-24.2)** in the Head Imaging Guidelines **AND/OR**
  - MR Spectroscopy (CPT® 76390)
  - Metabolic (FDG) PET Brain (CPT® 78608) **AND/OR**
  - CTA Head (CPT® 70496) OR MRA Head (CPT® 70544, CPT® 70545 or CPT® 70546) **AND/OR**
  - CTA Neck (CPT® 70498) OR MRA Neck without contrast (CPT® 70547), with contrast (CPT® 70548), or without and with contrast (CPT® 70549) OR
  - CTA Head and Neck (CPT® 70471) if performed during the same session **AND/OR**
  - 3D rendering CPT® 76377 (3D rendering requiring image post-processing on an independent workstation) or CPT® 76376 (3D rendering not requiring image post-processing on an independent workstation) is not necessary for epilepsy surgery alone, since 3D rendering can be obtained as part of the MRI Brain epilepsy protocol, unless complicated surgical repair considerations involving craniotomy are required.
  - Metabolic PET/MRI is MRI Brain without contrast (CPT® 70551) OR MRI Brain without and with contrast (CPT® 70553) co-registered with FDG-PET Brain (CPT® 78608) and is medically necessary for pre-surgical evaluation of refractory seizure when requested by neurosurgeon or neurologist or any provider in consultation with a neurosurgeon or neurologist.
- For additional imaging requests for surgery, see **Neurosurgical Imaging (HD-28)** in the Head Imaging Guidelines and/or **Primary Central Nervous System Tumors – General Considerations (ONC 2.1)** in the Oncology Imaging Guidelines.
- For intracranial monitoring with stereo-EEG or grids/strips and electrodes, additional imaging for neuronavigation is medically necessary with one each of the following, after consulting the health plan direction for unlisted codes:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551)
  - CT Head, contrast as requested
  - Due to variances with techniques currently available for neuronavigation, the following are medically necessary:
    - CTA Head (CPT® 70496) **OR** MRA Head (CPT® 70544, CPT® 70545 or CPT® 70546)
- Repeat diagnostic head imaging is medically necessary if previous head imaging is inadequate or additional sequences/protocols are required (including epilepsy protocol imaging) or previous imaging is greater than 6 months old.
- Post-operative imaging including after intracranial (EEG) monitoring is medically necessary per neurosurgeon's request.

Background and Supporting Information

Examples of epilepsy surgery and other interventional modalities include but are not limited to:

- Focal resection
- Temporal lobe resection
- Extratemporal resection
- Lesionectomy
- Multiple subpial transections
- Laser Interstitial Thermal Therapy (LITT)
- Anatomical or functional hemispherectomy and hemispherotomy
- Corpus callostomy
- Steretactic radiosurgery (SRS)
- Neurostimulation device implantations including the following:
  - Vagus nerve stimulation (VNS)
  - Responsive neurostimulation (RNS)
  - Deep brain stimulation (DBS)
- Magnetoencephalography (MEG) plays an important role in clarifying the significance of abnormalities seen on both structural and functional imaging, for the purpose of epileptogenic zone localization for surgical planning. When used in conjunction with other techniques, MEG plays a major role in the non-invasive epilepsy surgery evaluation. Currently, the guidelines only require review for the MRI co-registered with MEG. MEG followed by co-registration with MRI Brain is referred to as Magnetic Source Imaging (MSI).

Febrile Seizures (PEDHD-6.4)

HDP.EP.0006.4.A
v2.0.2026

- Neuroimaging should not be performed in the routine evaluation of children with simple febrile seizures.
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for febrile seizures in the presence of one or more of the following:
  - Seizure lasting >15 minutes
  - Focal onset seizures
  - Focal neurologic deficits
  - Multiple seizures within 24 hours
  - Macrocephaly (head circumference that is greater than the 97th percentile for age and sex, established by use of measurements and CDC growth charts. See **Macrocephaly (PEDHD-7.1)**)
  - Signs and symptoms of increased intracranial pressure
  - Developmental delay
  - MRI Brain permitted even with prior CT Head imaging
- CT Head without contrast (CPT® 70450) **OR** CT Head without and with contrast (CPT® 70470) is medically necessary for:
  - Concern for calcifications
  - For additional indications for CT Head, see **Pediatric Head Imaging Modality General Considerations (PEDHD-1.3)**.

Background and Supporting Information

- A typical febrile seizure is a generalized seizure occurring in the presence of fever (T >100.4°F/38°C) and no central nervous system infection in a child between the age of 6 months and 5 years.

Proprietary Information of UnitedHealthcare.

Macrocephaly (PEDHD-7.1)

HDP.MC.0007.1.A

v2.0.2026

Indications	Age or Condition	Medically Necessary Imaging Study
Head circumference that is greater than the 97th percentile for age and sex, or head circumference increasing in percentiles over two visits established by use of measurements and CDC growth charts (cdc.gov).	Birth to age 6 months or open fontanelle	◦ Ultrasound Head (CPT® 76506)
	Hydrocephalus or hemorrhage is present on ultrasound	◦ CT Head without contrast (CPT® 70450)
	Any abnormality seen on ultrasound	◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553) *MRI Brain permitted even with prior CT Head imaging*.
	Greater than 6 months old or closed fontanelle	◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553) *CT is not medically necessary in this age group since uncomplicated hydrocephalus is less likely after early infancy.*

Background and Supporting Information

- Macrocephaly is defined as head circumference that is greater than the 97th percentile for age and sex, or head circumference increasing in percentiles over two visits established by use of measurements and CDC growth charts (cdc.gov).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Microcephaly (PEDHD-7.2)

HDP.MC.0007.2.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for all individuals with head circumference that is less than the 3rd percentile for age and sex, or head circumference decreasing in percentiles over two visits established by use of measurements and CDC growth charts (cdc.gov).
  - CT is generally not recommended as that modality lacks the sensitivity to detect the relevant anatomical abnormalities.
  - For CT Head indications, see **Pediatric Head Imaging Modality General Considerations (PEDHD-1.3)**.

Background and Supporting Information

- Microcephaly is defined as head circumference that is less than the 3rd percentile for age and sex, or head circumference decreasing in percentiles over two visits established by use of measurements and CDC growth charts (cdc.gov).

Hydrocephalus, Shunts, and Endoscopic Third Ventriculostomy (ETV) (PEDHD-7.3)

HDP.MC.0007.3.A
v2.0.2026

Initial Imaging

Indication	Medically Necessary Imaging Study
Age 0-6 months	• Screening Ultrasound Head examination (CPT® 76506) • If ultrasound shows hydrocephalus, MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551)
Greater than 6 months old	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)
Siblings of individuals with aqueductal stenosis (familial screening for hydrocephalus is not otherwise medically necessary)	• One-time CT Head without contrast (CPT® 70450) **OR** • Rapid MRI Brain without contrast (CPT® 70551)

Proprietary Information of UnitedHealthcare.

Repeat Imaging in the Setting of VP Shunt and/or ETV

Indication	Medically Necessary Imaging Study
New signs or symptoms suggesting shunt malfunction or ETV malfunction, including (but not limited to): • Sepsis • Decreased level of consciousness • Protracted vomiting • Visual or neurologic deterioration • Decline of mentation after initial improvement • New or changing pattern of seizures	• Rapid MRI Brain without contrast (CPT® 70551) **OR** • CT Head without contrast (CPT® 70450)
• Post-operatively, or • After shunt setting adjustments, or • As ordered by a neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon	• Rapid MRI Brain without contrast (CPT® 70551) **OR** • CT Head without contrast (CPT® 70450)

Repeat Imaging of Ventriculomegaly

Indication	Medically Necessary Imaging Study
0-6 months old	• Serial US Head (CPT® 76506) to monitor ventricular size to determine need and timing of placement of a ventricular catheter, or performance of an endoscopic third ventriculostomy (ETV), timing as requested by the provider
Older than 6 months	• MRI Brain without and with contrast (CPT® 70553), timing as requested by the provider **OR** • MRI Brain without contrast (CPT® 70551), timing as requested by the provider

Proprietary Information of UnitedHealthcare.

Abdominal Imaging Indications in the Setting of VP Shunts

Indication	Medically Necessary Imaging Study
• Suspicion of CSF pseudocyst formation or distal shunt outlet obstruction • Surveillance imaging of the abdomen is medically necessary if ordered by a neurologist, neurosurgeon, or interventional radiologist, or in consultation with one of these providers	• Ultrasound Abdomen (CPT® 76700) **AND/OR** • CT Abdomen **OR** CT Abdomen and Pelvis, contrast as requested

Spine Imaging

Indication	Medically Necessary Imaging Study
Including, but not limited to the following: • Chiari malformation • Malignant infiltration of meninges	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR** • MRI Lumbar Spine without and with contrast (CPT® 72158) **OR** • MRI Lumbar Spine without contrast (CPT® 72148)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Dandy-Walker malformation	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141)

- For hydrocephalus due to choroid plexus papillomas, see **Choroid Plexus Tumors (PEDONC-4.13)** in the Pediatric and Special Populations Oncology Imaging Guidelines for those lesions.
- For CSF flow imaging, see **CSF Flow Imaging (HD-24.4)** in the Head Imaging Guidelines.

Additional Rarely Used Studies

- Cisternogram (CPT® 78630) is rarely done in children, but is medically necessary for the following:
  - Known hydrocephalus with worsening symptoms
  - Suspected obstructive hydrocephalus
  - Suspected normal pressure hydrocephalus with gait disturbance and either dementia or urinary incontinence
- Cerebrospinal Ventriculography (CPT® 78635) is rarely done in children, but is medically necessary for the following:
  - Evaluation of internal shunt, porencephalic cyst, or posterior fossa cyst
- Nuclear Medicine Shunt Evaluation (CPT® 78645) and CSF Flow SPECT (CPT® 78803) are rarely done in children, but are medically necessary for the following:
  - Suspected malfunction of ventriculoperitoneal, ventriculopleural, or ventriculovenous shunts

Background and Supporting Information

- Head ultrasound can be performed while the fontanelles are still open and has excellent spatial and anatomic resolution, particularly within the first 2 months of life. After 6 months, smaller acoustic windows due to closing fontanelles limit the sensitivity of the examination.
- Rapid MRI Brain without contrast (CPT® 70551) provides more anatomical detail and does not involve radiation exposure, but many providers use CT Head as rapid MRI is not universally available.
- Hydrocephalus is traditionally divided into non-communicating (the obstruction lies within the course of the brain's ventricular system) and communicating (the obstruction is distal to the ventricular system).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Ventriculomegaly refers to enlarged ventricular spaces. It is often initially found on fetal ultrasound. It can be from an obstructive cause or can be relative secondary to small brain volume.
- Benign enlargement of the subarachnoid space in infancy (BESSI), also called benign external hydrocephalus or benign extra-axial fluid collections is the rapid increase in head circumference in an infant with enlarged frontal subarachnoid spaces. See **Macrocephaly (PEDHD-7.1)** for initial imaging guidelines. It typically requires no intervention. Once diagnosed and confirmed with MRI Brain, no additional imaging is required unless new neurological symptoms appear, worsen, or persist beyond age 4 years. If developmental motor delay, see **Developmental Motor Delay (PEDHD 19.3)**.

Craniosynostosis Imaging (PEDHD-8.1)

HDP.CS.0008.1.A

v2.0.2026

- Skull x-rays and/or ultrasound should be obtained prior to considering advanced imaging. In cases of very strong consideration of craniosynostosis with surgical planning in progress, x-rays and/or ultrasound are not required.
- CT Head without contrast (CPT® 70450) is medically necessary in the diagnosis of craniosynostosis, with reported sensitivity near 100%. CT also detects associated intracranial pathology.
- 3D rendering (CPT® 76376 or CPT® 76377) is medically necessary with the initial diagnostic CT to evaluate the extent of synostosis and determine surgical candidacy or for preoperative planning.
- CT Maxillofacial without contrast (CPT® 70486) **AND** CT Orbits/Temporal Bone without contrast (CPT® 70480) are generally not medically necessary to evaluate individuals with craniosynostosis, but are medically necessary if the craniosynostosis is part of a larger congenital defect which also involves the bones of the face or orbit.
- CT Maxillofacial without contrast (CPT® 70486) **AND/OR** CT Orbits/Temporal Bone without contrast (CPT® 70480) is/are medically necessary in certain types of craniosynostosis and is/are medically necessary when ordered by surgical specialties or in consultation with surgical specialties during surgical evaluation and planning.
- Ultrasound Head (CPT® 76506) is medically necessary as an alternative method of assessing sutural patency in neonates and infants when radiographs are indeterminate. If inconclusive or for pre-operative planning, CT with 3D rendering is medically necessary as discussed previously in this section.
- CT Head without contrast (CPT® 70450) is medically necessary post-operatively at the discretion of or in consultation with the surgical specialist coordinating the individual's care.
- Positional plagiocephaly typically does NOT require advanced imaging.

Background and Supporting Information

- Craniosynostosis is the premature closure of one or more cranial sutures, usually during infancy.
- Craniosynostosis may be caused by a genetic condition, such as Apert, Pfeiffer, or Crouzon syndrome to name a few.
- Abnormal head shape is the common clinical feature.

Facial Anomalies (PEDHD-8.2)

HDP.CS.0008.2.A
v2.0.2026

- Congenital anomalies of facial structures
  - CT Maxillofacial without contrast (CPT® 70486) **OR** MRI Orbits/Face/Neck without contrast (CPT® 70540) **OR** MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
  - MRI Brain without contrast (CPT® 70551) is medically necessary in individuals with cleft lip and/or palate and encephalocele.
- See also **Craniosynostosis Imaging (PEDHD-8.1)**.

Background and Supporting Information

- Facial anomalies (such as cleft lip and palate) can be associated with brain malformations and abnormal brain development.
- Congenital anomalies of facial structures can include, but are not limited to:
  - Cleft lip/palate
  - Choanal atresia
  - Facial clefting
  - CHARGE syndrome
  - Nasofrontal dermoid
  - Encephalocele

Chiari Malformations (PEDHD-9.1)

HDP.CH.0009.1.A

v2.0.2026

- Ultrasound can be utilized for initial examination in infants to determine ventricular size and associated anomalies and to provide a baseline for follow-up evaluation but is not required prior to MRI.

Indication	Medically Necessary Imaging Study
◦ Initial evaluation for suspected or known Chiari malformations	Any of the following sets of imaging: MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR** MRI Cervical Spine without contrast (CPT® 72141) **OR** MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** MRI Thoracic Spine without contrast (CPT® 72146) **OR** MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR** MRI Lumbar Spine without contrast (CPT® 72148) **OR** MRI Lumbar Spine without and with contrast (CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
◦ Repeat imaging for any of the following: ▪ At the discretion of or in consultation with the neurologist and/or neurosurgeon coordinating the individual's care ▪ New or worsening signs or symptoms ▪ Surgical procedure is actively being considered	Any of the following sets of imaging: MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR** MRI Cervical Spine without contrast (CPT® 72141) **OR** MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** MRI Thoracic Spine without contrast (CPT® 72146) **OR** MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR** MRI Lumbar Spine without contrast (CPT® 72148) **OR** MRI Lumbar Spine without and with contrast (CPT® 72158)

- Familial screening is not medically necessary for Chiari I Malformations.
- For CSF flow imaging, see **CSF Flow Imaging (HD-24.4)** in the Head Imaging Guidelines.

Background and Supporting Information

- Chiari I malformations involve caudal displacement or herniation of the cerebellar tonsils. Chiari I may be associated with syringomyelia, and rarely with hydrocephalus. Most cases are asymptomatic and discovered incidentally on a head scan performed for another indication. When symptoms are present, they are usually nonspecific but can include headache, lower cranial nerve palsies, or sleep apnea.
- Chiari II malformations are more severe than Chiari I malformations. These individuals usually present at birth. Myelomeningocele is always present, and syringomyelia and hydrocephalus are extremely common.
- Chiari III malformations include cerebellar herniation into a high cervical myelomeningocele. Chiari IV malformations refer to complete cerebellar agenesis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Both Chiari III and IV malformations are noted at birth and are rarely compatible with life.

- Repeat brain and spine imaging in individuals with Chiari I malformations and known syringomyelia or hydromyelia is highly individualized.

Pediatric Intracranial Aneurysms and Subarachnoid Hemorrhage (PEDHD-10.1)

HDP.IA.0010.1.A
v2.0.2026

- A pertinent evaluation including a detailed history, physical examination with a thorough neurologic examination, and appropriate laboratory studies should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled follow-up imaging evaluation or request is from a neurologist or neurosurgeon who has seen the individual since onset of symptoms.
- MRI Brain permitted even with prior CT Head imaging
- MRI Perfusion is obtained with MRI Brain (CPT® 70551 **OR** CPT® 70552 **OR** CPT® 70553).
  - No additional CPT® codes are necessary or appropriate to perform MRI perfusion.
- Initial study for suspected subarachnoid hemorrhage:
  - CT Head without contrast (CPT® 70450) **AND/OR**
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553)
- If subarachnoid hemorrhage is present on CT or MRI, or lumbar puncture findings suggest hemorrhage, then the following is/are medically necessary:
  - MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR**
  - CTA Head (CPT® 70496) **AND/OR**
  - CT Brain Perfusion (CPT® 70472 or 70473) or MRI Brain Perfusion (CPT® 70553)
- Initial study for suspected intracranial aneurysym - individuals presenting with headache, increased intracranial pressure, seizures, or focal neurologic findings:
  - CT Head without contrast (CPT® 70450) **AND/OR**
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553)
- If findings suspicious for intracranial aneurysm on prior imaging, then the following is supported:
  - MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR**
  - CTA Head (CPT® 70496)
- Imaging for individuals with known aneurysm presenting with headache, increased intracranial pressure, seizures, or focal neurologic findings:
  - CT Head without contrast (CPT® 70450) **AND/OR**
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - MRA Head (CPT® 70544, CPT® 70545 **OR** CPT® 70546) **OR**

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

  - CTA Head (CPT® 70496)
- CT Head without contrast (CPT® 70450) **AND/OR** MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR** MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** CTA Head (CPT® 70496) (except in the case of multisystemic smooth muscle syndrome (MSMS)/smooth muscle dysfunction syndrome (SMDS)/ACTA2 mutations, (see **HD-21.7** in the Head Imaging Guidelines)) is/are medically necessary for individuals with headache, increased intracranial pressure, seizures, or focal neurologic findings **AND** any of the following conditions (including but not limited to):
  - Aicardi–Goutières syndrome
  - Alpha-1-antitrypsin deficiency
  - Alpha-glucosidase deficiency
  - Azygos anterior cerebral artery
  - Bicuspid aortic valve
  - Coarctation of the aorta (for screening of intracranial aneurysms, see **Aortic Coarctation and IAA (interrupted aortic arch) (PEDCD-2.4.11)**)
  - Ehlers-Danlos Syndrome
  - Fibromuscular dysplasia
  - Hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome)
  - Hyper-IgE syndrome
  - Kawasaki disease
  - Klinefelter syndrome
  - Klippel-Trenaunay-Weber syndrome
  - Loeys-Dietz syndrome (there are 4 forms)
  - Marfan syndrome
  - Microcephalic osteodysplastic primordial dwarfism type II
  - Moyamoya syndrome
  - Multisystemic smooth muscle syndrome (MSMS)/smooth muscle dysfunction syndrome (SMDS)/ACTA2 mutations (See **HD-21.7**)
  - Neurofibromatosis type 1
  - Noonan syndrome
  - Patent ductus arteriosus
  - Pheochromocytoma
  - Pseudoxanthoma elasticum
  - Polycystic kidney disease
  - Tuberous sclerosis
- The timing of follow-up imaging for intracranial aneurysms in children is similar to that in adults. See **Intracranial Aneurysms (HD-12.1)** in the Head Imaging Guidelines.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- Screening for intracranial aneurysms is not medically necessary in individuals with coarctation of the aorta repaired before 3 years of age. See **Intracranial Aneurysms (HD-12.1)** in the Head Imaging Guidelines.
- Screening is not medically necessary in asymptomatic individuals under 20 years of age, unless there are 2 or more first-degree relatives with intracranial aneurysm. See **Intracranial Aneurysms (HD-12.1)** in the Head Imaging Guidelines.

Background and Supporting Information

- Unlike adults, the majority of pediatric aneurysms are caused by genetic or developmental defects rather than environmental or lifestyle factors.
- Pediatric aneurysms most commonly present with subarachnoid hemorrhage, headache, increased intracranial pressure, seizure activity, or focal neurologic findings.

Pediatric Intracranial Arteriovenous Malformations (AVM) (PEDHD-10.2)

HDP.IA.0010.2.A
v2.0.2026

- A pertinent evaluation including a detailed history, physical examination with a thorough neurologic examination, and appropriate laboratory studies should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled follow-up imaging evaluation or request is from or in consultation with a neurologist or neurosurgeon who has seen the individual since onset of symptoms.
- Use this guideline for cerebral vascular malformations including arteriovenous, venous, cavernous, and capillary malformations and vein of Galen malformations.

Disorders	Indications (any of the following)	Medically Necessary Imaging Study
• Any cerebral vascular and/or AVM Disorder listed in this guideline	• When MRI is contraindicated • Any emergency setting	• CT Head without contrast (CPT® 70450) **AND/OR** • CTA Head (CPT® 70496) **AND/OR** • CTA Neck (CPT® 70498) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Disorders	Indications (any of the following)	Medically Necessary Imaging Study
• Suspected Vein of Galen malformation in the neonate	• Confirmation by Ultrasound Head (CPT® 76506)	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • Catheter Angiography to precisely identify the feeding arteries and draining vein, especially if embolization is planned
• Low flow malformations	• When requested by a neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon	• MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** • CTA Head (CPT® 70496)
• Suspected AVM after the neonatal period	• When requested by a neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)

Proprietary Information of UnitedHealthcare.

Disorders	Indications (any of the following)	Medically Necessary Imaging Study
• Known AVM	• When requested by a neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** • CTA Head (CPT® 70496)
• Hereditary Hemorrhagic Telangiectasia (HHT, Osler-Weber-Rendu syndrome)	• Suspected based on family history with at least one affected first-degree relative. (biological parent or sibling or child) • At diagnosis • Screening for confirmed HHT • Clinical signs or symptoms concerning for disease progression • When requested by a neurologist, neurosurgeon, geneticist, or any provider in consultation with a neurologist or neurosurgeon or geneticist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545 **OR** CPT® 70546) **OR** • CTA Head (CPT® 70496)

Disorders	Indications (any of the following)	Medically Necessary Imaging Study
• Capillary malformation-arteriovenous malformation (CM-AVM)	• Suspected based on family history with at least one affected first-degree relative (biological parent or sibling or child) • At diagnosis • Screening for confirmed CM-AVM • Clinical signs or symptoms concerning for disease progression • When requested by a neurologist, neurosurgeon, geneticist, or any provider in consultation with a neurologist or neurosurgeon or geneticist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545 **OR** CPT® 70546) **OR** CTA Head (CPT® 70496) **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **OR** MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** MRI Thoracic Spine without contrast (CPT® 72146)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Disorders	Indications (any of the following)	Medically Necessary Imaging Study
• Cerebral cavernous malformations (CCM)	• Suspected based on family history with at least one affected first-degree relative (biological parent or sibling or child). • At diagnosis • Screening for confirmed CCM • Clinical signs or symptoms concerning for disease progression • When requested by a neurologist, neurosurgeon, geneticist, or any provider in consultation with a neurologist or neurosurgeon or geneticist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545 **OR** CPT® 70546) **OR** • CTA Head (CPT® 70496) **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146)

Disorders	Indications (any of the following)	Medically Necessary Imaging Study
• Microcephalic osteodysplastic primordial dwarfism, type II (MOPDII)	• Suspected based on family history with at least one affected first-degree relative (biological parent or sibling or child) • At diagnosis • Screening for confirmed MOPDII, repeated annually • Clinical signs or symptoms concerning for disease progression • When requested by a neurologist, neurosurgeon, geneticist, or any provider in consultation with a neurologist or neurosurgeon or geneticist	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** • CTA Head (CPT® 70496) **AND/OR** • MRA Neck without contrast (CPT® 70547, CPT® 70548 **OR** CPT® 70549) **OR** • CTA Neck (CPT® 70498) **OR** • CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session.
• Sturge-Weber syndrome	• At diagnosis • Clinical signs or symptoms concerning for disease progression • When requested by a neurologist, neurosurgeon, or any provider in consultation with a neurologist or neurosurgeon	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRI Orbits/Face/Neck without and with contrast (CPT® 70543) **OR** • MRI Orbits/Face/Neck without contrast (CPT® 70540)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Additional indications

- CT Head without contrast (CPT® 70450) is medically necessary for ANY one of the following:
  - Mass effect
  - Urgent/emergent settings due to availability and speed of CT
  - Trauma
  - Recent hemorrhage, whether traumatic or spontaneous
  - Prior to lumbar puncture in individuals with cranial complaints
  - Scenarios in which MRI is contraindicated (e.g., pacemakers, ICDs, cochlear implants, aneurysm clips, orbital metallic fragments, etc.)
- Prior CT Head (CPT® 70450) does not exclude indication for MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551).

Background and Supporting Information

- Most intracranial AVMs are congenital, vary widely in their location and type, and are discovered at birth due to associated clinical findings or incidentally later in life. Certain hereditary conditions are associated with an increased risk for AVM development.
- Vascular malformations include arteriovenous, venous, cavernous, and capillary malformations. The vein of Galen malformation is the most common arteriovenous malformation, presenting in neonates with signs of high output congestive heart failure or later in infancy of childhood with signs of hydrocephalus. Low flow venous, cavernous, and capillary malformations may be asymptomatic and discovered incidentally, or they may present in childhood with seizures or neurologic findings secondary to intracranial hemorrhage.
- Hereditary AVMs usually have an autosomal dominant pattern of inheritance.

Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Syncope (PEDHD-11.1)

HDP.SY.0011.1.A

v2.0.2026

- Advanced imaging of the brain is not medically necessary for individuals with isolated syncope without focal neurologic findings. See **Syncope (PEDCD-5)** in the Pediatric Cardiac Imaging Guidelines and **Epilepsy and Other Seizure Disorders (PEDHD-6)** for additional imaging considerations.

Background and Supporting Information

- Syncope in children is almost always neurocardiogenic (vasovagal) in nature. Intracranial mass lesions do not cause isolated syncope. Syncope and seizure activity can often be challenging to distinguish for unwitnessed syncope.
- There is no role for advanced neuroimaging for Postural Orthostatic Tachycardia Syndrome (POTS).

Proprietary Information of UnitedHealthcare.

Pediatric Stroke General Considerations (PEDHD-12.1)

HDP.PS.0012.1.A
v2.0.2026

- Imaging indications are the same for neonates as for older children.
- Children may not present with typical stroke findings.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pediatric Stroke Initial Imaging (PEDHD-12.2)

HDP.PS.0012.2.A

v2.0.2026

- In the presence of neurological signs and/or symptoms with concern for stroke, **ANY** of the following studies are medically necessary:
  - CT Head without contrast (CPT® 70450) **OR** MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553)
  - MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** CTA Head (CPT® 70496)
  - For suspected carotid or vertebral artery dissection, CTA Neck (CPT® 70498) **OR** MRA Neck (CPT® 70547, CPT® 70548, **OR** CPT® 70549) **OR**
  - CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session.
  - Note: Both MRA **OR** CTA Head **AND** Neck are needed to visualize the posterior vertebrobasilar circulation for evaluation of the vertebrobasilar stroke/TIA (vertigo associated with diplopia, dysarthria, bifacial numbness or ataxia) or concern for arterial dissection (risks may include premature stroke [under age 50], head or neck trauma, fibromuscular dysplasia, Ehlers-Danlos syndrome, and chiropractic neck manipulation)
- In individuals with COVID-19, see **COVID-19 and Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDHD-12.7)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pediatric Stroke Subsequent Imaging (PEDHD-12.3)

HDP.PS.0012.3.A

v2.0.2026

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for any new or worsening neurological findings or seizure activity.
- Repeat imaging for follow-up and resolution of stroke or hemorrhage as determined by a neurologist, neurosurgeon, hematologist, or physiatrist (PM&R), or any provider in consultation with a neurologist, neurosurgeon, hematologist, or physiatrist (PM&R).
  - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553)
  - MRA Head/MRV Head (CPT® 70544, CPT® 70545 **OR** CPT® 70546) **OR** CTA Head/CTV Head (CPT® 70496) for follow-up of known cerebral artery stenosis or thrombosis
  - Other surveillance imaging indications after stroke are listed in the disease-specific sections.

Background and Supporting Information

- CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography):
  - If arterial and venous CT or MR studies are both performed in the same session, only **one** CPT® code is used to report both procedures.
  - If an arterial CTA **OR** MRA study has been performed and subsequently a repeat study is needed to evaluate the venous anatomy, then this study is medically necessary.
  - If a venous CTV **OR** MRV study has been performed and subsequently a repeat study is needed to evaluate the arterial anatomy, then this study is medically necessary.
  - MRA without and with contrast with venous sinus thrombosis to differentiate total from subtotal occlusion

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Sickle Cell Disease (PEDHD-12.5)

HDP.PS.0012.5.A

v2.0.2026

- The following imaging is medically necessary for all sickle cell individuals with a severe phenotype (Hgb SS or Hgb $S\beta^0$):
  - Transcranial Doppler (TCD) Ultrasound (CPT® 93886 or CPT® 93888) annually for all individuals aged 2 to 16:
    - A short interval repeat study is medically necessary for individuals with conditional (170-199cm/sec) flow results, or with individuals undergoing transfusion therapy.
  - Transcranial Doppler (TCD) Ultrasound (CPT® 93886 or CPT® 93888) for children aged 17 years old may be appropriate on a case-by-case basis.
    - See also **Stroke/TIA (HD-21.1)** in the Head Imaging Guidelines.
  - After 17 years old, for individuals with a history of abnormal TCDs, TCDs may be repeated every 3 months.
  - TCD is not medically necessary for individuals with other phenotypes (Hgb SC, Hgb $S\beta^+$).
  - See indications below for advanced imaging with MR or CT.
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for any of the following:
  - Two non-imaging Transcranial Doppler (TCD) measurements of ≥200cm/sec or a single measurement of >220cm/sec or 2 assessment TCD measurements ≥185cm/sec or a single measurement >205cm/sec.
  - Persistently abnormal TCD velocities
    - For more regarding TCD, see **Background and Supporting Information**.
  - Screening to detect silent cerebral infarcts
  - New symptoms or cognitive impairment occurs or a change in academic performance
  - After an infarct-like lesion is identified, repeat every 12-24 months to assess for cerebral infarct progression
  - Prior to any change in therapy

Background and Supporting Information

- TCD is used to screen for overt and silent infarctions and monitor response to transfusion therapy.
- Individuals with sickle cell disease are at significantly increased risk for stroke and silent infarction, beginning at a very young age. Recent advances allow physicians to identify individuals at high risk for stroke and begin a primary stroke prevention program.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Identification of silent cerebral infarction is important because treatment with prophylactic red cell transfusions to maintain hemoglobin S levels at <30% of total hemoglobin may reduce recurrent stroke and extent of neurologic damage.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CNS Vasculitis (PEDHD-12.6)

HDP.PS.0012.6.A
v2.0.2026

- Medically necessary initial imaging for concern for primary CNS vasculitis, or for individuals with systemic vasculitis and suspected CNS involvement include the following:
  - MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR**
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR**
  - CTA Head (CPT® 70496) **AND/OR**
  - CTA Neck (CPT® 70498) **OR**
  - CTA Head and Neck (CPT® 70471) if performed during the same session.
- If MRI findings are suggestive of vasculitis, the following is medically necessary:
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR**
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR**
  - CTA Head (CPT® 70496) **AND/OR**
  - CTA Neck (CPT® 70498) **OR**
  - CTA Head and Neck (CPT® 70471) if performed during the same session.
- The following are medically necessary for treatment response and/or surveillance imaging as ordered by a neurologist, rheumatologist, or neurosurgeon, or in consultation with one of these providers:
  - MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR**
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR**
  - CTA Head (CPT® 70496) **AND/OR**
  - CTA Neck (CPT® 70498) **OR**
  - CTA Head and Neck (CPT® 70471) if performed during the same session.

Background and Supporting Information

- A normal MRI Brain almost always completely excludes intracranial vasculitis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

COVID-19 and Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDHD-12.7)

HDP.PS.0012.7.A
v2.0.2026

- If concern for CNS infection, see **CNS Infection (PEDHD-29.1)**.
- For cardiac imaging, see **Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDCD-12)**

  in the Pediatric Cardiac Imaging Guidelines.
- Symptoms of MIS-C may include some or all of the following:
  - Headache **AND/OR** irritability
  - Mucocutaneous changes similar to Kawasaki disease (i.e., strawberry tongue, red cracked lips, rash of hands and/or feet)
  - Polymorphus **AND/OR** vasculitic rash
  - Non-exudative conjunctivitis
  - Tachycardia **AND/OR** hypotension
  - Cough **AND/OR** shortness of breath
  - Abdominal pain, vomiting, **AND/OR** diarrhea
  - Lymphadenopathy, joint pain, **AND/OR** sore throat

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
◦ Imaging for neurological signs and/or symptoms, including headache, after known or presumed COVID-19 infection	◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553) **AND/OR** ◦ MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** ◦ CTA Head (CPT® 70496) **AND/OR** ◦ MRA Neck (CPT® 70547, CPT® 70548, **OR** CPT® 70549) **OR** ◦ CTA Neck (CPT® 70498) **OR** ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session.

Background and Supporting Information

- COVID-19 infections in children are generally mild in comparison to that of adults. However a post-viral syndrome in children has become increasingly noted.
- Multisystem Inflammatory Syndrome in Children (MIS-C) can cause an inflammatory vasculopathy, prothrombotic state, and/or post-viral myocarditis in children who have had a COVID-19 infection caused by SARS-CoV-2. The child may have had minor symptoms or been asymptomatic at the time of COVID-19 infection, but the virus can trigger endothelial injury and activation of the IL-1 pathway similar to that in Kawasaki disease and acute rheumatic fever.

Pediatric Demyelinating Disease General Considerations (PEDHD-14.1)

HDP.DD.0014.1.A

v2.0.2026

- For evaluation of pediatric demyelinating disease, the following imaging is medically necessary:
  - MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR**
  - MRI Thoracic Spine without and with contrast (CPT® 72157)
- MRI Lumbar Spine without and with contrast (CPT® 72158) is not medically necessary unless the individual has a tethered cord or other anatomic abnormality causing caudal displacement of the filum terminalis.
- CT imaging is generally **NOT** medically necessary in the evaluation of demyelinating disease.
- Metabolic (FDG) PET Brain (CPT® 78608) and MR Spectroscopy (CPT® 76390) are considered not medically necessary for evaluation of pediatric demyelinating diseases.
- For metabolic or genetic white matter disorders, including leukodystrophies and mitochondrial disorders, see **Neurometabolic and Neurogenetic Disorders (PEDHD-19.4)**.

Multiple Sclerosis (MS) (PEDHD-14.2)

HDP.DD.0014.2.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial diagnosis in individuals with clinical signs and/or symptoms suggestive of MS	• MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) If there is a contraindication to gadolinium administration, then • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Disease monitoring whether or not receiving treatment	Every 6 months or for new signs/ symptoms: • MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) Every 12 months or for new signs/ symptoms: • MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146)
Optic neuritis suspected	• MRI Orbits/Face/Neck without and with contrast (CPT® 70543) may be added If there is a contraindication to gadolinium administration, then • MRI Orbits/Face/Neck without contrast (CPT® 70540) may be added
Symptoms suggestive of Progressive multifocal leukoencephalopathy (PML) during natalizumab (Tysabri®) therapy (or other medications with similar risk)	• MRI Brain without and with contrast (CPT® 70553) If there is a contraindication to gadolinium administration, then ◦ MRI Brain without contrast (CPT® 70551)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Screening for individuals on natalizumab (Tysabri®) or other drugs with risk of progressive multifocal leukoencephalopathy (PML)	Every 6 months while on treatment: • MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) Every 3-6 months for high-risk individuals positive for serum JC virus antibody and >18 months natalizumab exposure: • MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)
If MRI Brain without contrast (CPT® 70551) shows incidental evidence of possible demyelinating disease	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain with contrast (CPT® 70552)
After an MRI Brain without contrast (CPT® 70551), a follow-up MRI brain may be performed at the discretion of a neurologist, a neurosurgeon, or a neuro-ophthalmologist, or any provider in consultation with a neurologist, neurosurgeon, or neuro-ophthalmologist, and/or at the recommendation of the radiologist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain with contrast (CPT® 70552)

Background and Supporting Information

- Multiple sclerosis is less common in children. About 4% of MS cases are diagnosed before age 18, and only ~0.7% of all MS cases begin before age of 10 years.
- Common presentations of MS in children include ataxia, optic neuritis, diplopia, transverse myelitis or as an acute encephalitis-like illness.
- Among children with suspected demyelinating diseases, the principal differential diagnosis is often between MS, Acute Disseminated Encephalomyelitis (See **Acute Disseminated Encephalomyelitis (ADEM) and Other Pediatric Demyelinating Disorders (PEDHD-14.3)** or MOG Antibody-Associated Disease (MOGAD). (See **MOG Antibody-Associated Disease (MOGAD) (HD-16.3)**).
- Medications with similar risks of Progressive Multifocal Leukoencephalopathy (PML) as Tysabri® include: dimethyl fumarate (Tecfidera®), fingolimod (Gilenya®),

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

ocrelizumab (Ocrevus®), clardribine (Mavenclad®), diroximel fumarate (Vumerity®), eculizaumab (Soliris®), ozanimod (Zeposia®), alemtuzumab (Lemtrada®), monomethyl fumarate (Bafiertam®), rituximab (Rituxan®).

- If a non-contrast study shows incidental evidence of possible demyelinating disease, repeat imaging is appropriate as the presence of enhancing lesions may be helpful in confirming the diagnosis.
- 3D imaging in the evaluation of Multiple Sclerosis is not supported as a separate code. Most scanners are capable of 3D acquisitions or other imaging sequences.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Acute Disseminated Encephalomyelitis (ADEM) and Other Pediatric Demyelinating Disorders (PEDHD-14.3)

HDP.DD.0014.3.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) **AND/OR** MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** MRI Thoracic Spine without and with contrast (CPT® 72157) are medically necessary as the initial imaging in individuals with clinical signs and/or symptoms suggestive of ADEM OR for follow-up imaging when ordered by a neurologist or any provider in consultation with a neurologist.
  - MRI Brain without contrast (CPT® 70551) **AND/OR** MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** MRI Thoracic Spine without contrast (CPT® 72146) are medically necessary if there is a contraindication to gadolinium.
- Other pediatric demyelinating disorders that have clinical overlap with multiple sclerosis and ADEM include, but are not limited to:
  - **Neuromyelitis Optica Spectrum Disorders (HD-16.2)**
  - **Anti-MOG Syndromes (HD-16.3)**
  - **Traverse myelitis (HD-16.4)**
- For metabolic or genetic white matter disorders, including leukodystrophies and mitochondrial disorders, see **Neurometabolic and Neurogenetic Disorders (PEDHD-19.4)**.

Background and Supporting Information

- ADEM has an acute onset, and is more common among younger children than MS, but the signs and symptoms overlap significantly and distinguishing between MS and ADEM can be challenging based on clinical examination alone.
- Most individuals will have complete clinical recovery by 12 months, while stable MRI abnormalities (gliosis) may persist. These findings do not require additional imaging unless the individual develops new neurologic symptoms. Prolonged symptoms or return of symptoms may represent a different demyelinating disorder.

Proprietary Information of UnitedHealthcare.

Pituitary Dysfunction General Considerations (PEDHD-15.1)

HDP.PD.0015.1.A

v2.0.2026

- The initial step in the evaluation of all potential pituitary masses is a detailed history, recent physical examination, and thorough neurological exam, including evaluation of the visual fields.
- Endocrine laboratory studies should be performed prior to considering initial advanced imaging.
- MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) when pituitary imaging is medically necessary.
  - Pituitary Gland: one study (either MRI Brain without and with contrast [CPT® 70553] **OR** MRI Orbits/Face/Neck [CPT® 70543]) is adequate to report the imaging of the pituitary. The reporting of two CPT® codes to image the pituitary is not medically necessary.
- If a previous MRI Brain was reported to show a possible pituitary tumor with supporting evidence of pituitary disease or is inconclusive, a repeat MRI with dedicated pituitary protocol may be performed. If a prior MRI Brain was without contrast, a follow-up scan either MRI Brain with contrast (CPT® 70552) **OR** MRI Brain without and with contrast (CPT® 70553) is appropriate.
- For association between pituitary dysfunction and optic nerve issues, see **Eye Disorders and Visual Loss (HD- 32.1)** in the Head Imaging Guidelines.
- For repeat imaging, see **Pituitary, Sella, Hypothalamus (HD-19.1)** in the Head Imaging Guidelines.

Click Here to Return to the Main TOC

Panhypopituitarism (PEDHD-15.2)

HDP.PD.0015.2.A
v2.0.2026

- Endocrine testing should be performed initially.
- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) with special attention to the pituitary is medically necessary for newly diagnosed Panhypopituitarism.
- Individuals with a normal pituitary on initial MRI do not need routine follow-up imaging.
- Individuals with mass lesions should have follow-up imaging according to the guidelines for the specific diagnosis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Isolated Growth Hormone Deficiency (PEDHD-15.3)

HDP.PD.0015.3.A

v2.0.2026

- Clinical features include: height below the normal range (<3rd percentile), subnormal growth velocity or the child's height is below the range expected based on parental height.
- Risk factors include: a history of brain tumor, cranial irradiation, or other congenital/ organic hypothalamic-pituitary abnormality as well as an incidental finding of a hypothalamic-pituitary abnormality on MRI.
- Endocrine testing should be performed initially.
- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) with special attention to the pituitary is medically necessary for any of the following:
  - Both IGF1 and IGFBP3 are below the laboratory reference range for age/sex or Tanner stage.
  - 2 measurements of growth hormone stimulation with different stimulation agents (glucagon, clonidine, arginine, insulin, levodopa) performed on the same day or separate days produce maximal GH levels <10ng/mL. See **Background and Supporting Information.**
- Individuals with a normal pituitary on initial MRI do not need routine follow-up imaging.
- Individuals with mass lesions should have follow-up imaging according to the guidelines for the specific diagnosis.

Background and Supporting Information

- Growth hormone stimulation testing is limited by poor specificity and requires failure on 2 tests to diagnose growth hormone deficiency.
- Controversy exists as to the cutoff level which differentiates a normal response from a deficient response on provocative testing. Some experts support GH <7ng/mL however many pediatric endocrinologists consider a peak GH level <10ng/mL to be indicative of growth hormone deficiency and may identify children with partial GHD.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Diabetes Insipidus (DI) and Other Disorders of Anti-Diuretic Hormone (PEDHD-15.4)

HDP.PD.0015.4.A

v2.0.2026

- Laboratory testing should be performed initially. Diabetes insipidus is characterized by serum osmolality >300mOsm/kg and urine osmolality <300mOsm/kg.
- Central diabetes insipidus (CDI) is caused by diminished synthesis or secretion of vasopressin in the hypothalamus and nephrogenic diabetes insipidus (NDI) is caused by renal resistance to vasopressin.

Central Diabetes Insipidus (DI)

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for newly diagnosed central DI.
- Individuals with a normal pituitary on initial MRI can have repeat MRI Brain without and with contrast (CPT® 70553) every 3-6 months for the first 2 years as germinomas may cause central DI while still too small to detect on imaging.
  - Serial measurement of β -hCG is also medically necessary for these individuals, and MRI should be repeated if a significant rise in β -hCG is detected on screening.
- Individuals with mass lesions should have follow-up imaging according to the guidelines for the specific diagnosis.

Nephrogenic DI

- Once this diagnosis is firmly established, further advanced imaging is usually not medically necessary.

Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH)

- Laboratory studies should be obtained prior to considering advanced imaging—urine osmolality should be high and serum osmolality low.
- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for initial evaluation of unexplained central (hypothalamic pituitary) SIADH.
- Individuals with a normal pituitary on initial MRI do not need routine follow-up imaging.
- Individuals with mass lesions should have follow-up imaging according to the guidelines for the specific diagnosis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- See **Small Cell Lung Cancer-Suspected/Diagnosis (ONC-7.1)** and **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.
- Pulmonary diseases including infection (tuberculosis, viral/bacterial pneumonia), acute respiratory infections, mechanical ventilation and others can cause SIADH although the mechanism is unclear. Individuals with lung disease should have chest imaging according to the guidelines for the specific diagnosis.

Proprietary Information of UnitedHealthcare.

Precocious Puberty (PEDHD-15.5)

HDP.PD.0015.5.A

v2.0.2026

- Defined as the appearance of secondary sexual characteristics before age 8 in females and before age 9 in males. The diagnosis is made clinically using Tanner staging and often will include a bone age assessment (hand/wrist radiographs) and/or abdominal and/or pelvic ultrasound (See Peripheral Precocious Puberty below).
- Endocrine laboratory studies (baseline LH, FSH and either estradiol or testosterone) are used to determine if the etiology of precocious puberty is central (gonadotropin dependent) or peripheral (gonadotropin independent). Estradiol and testosterone levels will often be elevated to a pubertal range.

Central Precocious Puberty (CPP)

- An LH >0.3U/L on a random blood sample is the most reliable screening test for central precocious puberty. If LH <0.3U/L and CPP is suspected, a stimulation test with a GnRH analog is the gold standard.
- Neuroimaging should always follow hormonal studies that suggest a central origin of precocious puberty.
- MRI Brain without and with contrast (CPT® 70553, preferred study) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for evaluation of any child with documented central precocious puberty.
- MRI is appropriate irrespective of age and gender in individuals with precocious puberty and concurrent CNS symptoms of severe headache, visual changes, or seizures.
- Individuals with a normal pituitary on initial MRI do not need routine follow-up imaging.
- Individuals with mass lesions should have follow-up imaging according to the guidelines for the specific diagnosis. (**Benign Pituitary Tumors (PEDHD-15.6**) and **Pituitary Malignancies (PEDHD-15.7)**)

Peripheral Precocious Puberty

- The differential diagnosis of peripheral precocious puberty (LH suppressed or in the pre-pubertal range with elevated estradiol, testosterone, and/or adrenal androgens) is broad and may include ovarian, testicular, adrenal, and other sources of excessive hormonal production.
- Ultrasound Abdomen (CPT® 76700) in both genders and Ultrasound Pelvis (CPT® 76856) in females and Scrotal ultrasound (CPT 76870) in males depending on the suspected source of hormonal excess for initial imaging.

Hearing Loss (PEDHD-16.1)

HDP.ED.0016.1.A
v2.0.2026

- A pertinent evaluation including a detailed history, physical examination (including otoscopic examination), and age-appropriate audiology testing should be performed on any child with known or suspected hearing loss prior to considering advanced imaging. The selection of imaging testing will depend on the age of the child and type of hearing loss.
- CT Orbits/Temporal Bone without contrast (CPT® 70480) is medically necessary for the following:
  - Conductive hearing loss of any cause
  - Pre-operative planning for resection of mass lesion or cochlear implant placement
  - Sensorineural hearing loss in individuals who cannot safely undergo MRI
  - Mixed conductive and sensorineural hearing loss
  - Congenital hearing loss
  - Total deafness
- MRI Brain without and with contrast (CPT® 70553) with attention to internal auditory canals (included in CPT® 70553 and does not require a separate CPT® code) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for the following:
  - Conductive hearing loss secondary to known or suspected mass lesion
  - Pre-operative planning for resection of mass lesion or cochlear implant placement
  - Sensorineural hearing loss of any cause
  - Mixed conductive and sensorineural hearing loss
  - Congenital hearing loss
  - Total deafness
  - For hearing loss associated with tinnitus, see **Tinnitus (PEDHD-16.5)**.
- Both modalities (CT and MRI) are supported simultaneously for evaluation and surgical planning if ordered by or in consultation with an ENT or neurosurgical specialist.
- Limited MRI Brain with attention to internal auditory canals (CPT® 70540, CPT® 70542, or CPT® 70543) is medically necessary when requested by the provider in place of a complete MRI Brain. Note: Limited MRI codes should not be used in addition to MRI Brain codes; IAC views are performed as additional sequences as part of the brain study. (See **General Guidelines – Anatomic Issues (HD-1.1)** in the Head Imaging Guidelines)

Ear Pain (PEDHD-16.2)

HDP.ED.0016.2.A
v2.0.2026

- A pertinent evaluation including a detailed history, physical examination (including otoscopic examination), should be performed on any child with ear pain prior to considering advanced imaging. Common causes of ear pain include external and middle ear infections, dental problems, sinus infection, neck problems, and referred pain from the oral pharynx, tonsillitis, and pharyngitis.
- Advanced imaging is not medically necessary in the overwhelming majority of pediatric individuals with ear pain.

Indications	Medically Necessary Imaging Study
◦ Any of the following ▪ Persistent ear pain without obvious cause ▪ Clinical suspicion for complicated or invasive infection such as mastoiditis ▪ Clinical suspicion of mass lesion causing ear pain ▪ Significant trauma with concern for hematoma formation ▪ Pre-operative planning	◦ ONE of the following: ▪ CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR** ▪ CT Orbits/Temporal Bone without and with contrast (CPT® 70482) **OR** ▪ MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) **OR** ▪ MRI Orbits/Face/Neck without and with contrast (CPT® 70543)

Proprietary Information of UnitedHealthcare.

Cholesteatoma (PEDHD-16.3)

HDP.ED.0016.3.A
v2.0.2026

- ONE of the following studies is medically necessary for pre-operative evaluation in children with cholesteatoma:
  - CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR**
  - CT Orbits/Temporal Bone without and with contrast (CPT® 70482) **OR**
  - MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553), **OR**
  - MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
- ONE of the following studies is medically necessary one time post-operatively to exclude residual or regrown cholesteatoma to avoid the need for a second-look surgery:
  - CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR**
  - CT Orbits/Temporal Bone without and with contrast (CPT® 70482) **OR**
  - MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) **OR**
  - MRI Orbits/Face/Neck without and with contrast (CPT® 70543)

Background and Supporting Information

- Cholesteatomas are expansive cysts of the middle ear filled with cellular debris. They can be congenital or arise from recurrent middle ear infections or trauma to the tympanic membrane. Hearing loss is usually conductive, although if the lesion is large enough combined conductive and sensorineural hearing loss may be present. Otoscopic exam findings and symptoms may include a white mass in the middle ear cleft, painless drainage from the ear or chronic/recurrent ear infections. Advanced imaging for the diagnosis and management of suspected cholestatoma, in particular, should be reserved for the otolaryngologist or provider in consultation with the otolaryngologist.

Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Vertigo (PEDHD-16.4)

HDP.ED.0016.4.A

v2.0.2026

- A pertinent evaluation including a detailed history, physical examination (including otoscopic examination), should be performed on any child with vertigo prior to considering advanced imaging.
- If physical examination is otherwise normal and the vertigo responds to treatment, advanced imaging is not medically necessary.
- MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) is medically necessary for the following:
  - Vertigo with associated headache or ataxia
  - Vertigo associated with tinnitus
  - Vertigo that does not respond to vestibular treatment

Background and Supporting Information

Isolated vertigo is an uncommon complaint during childhood. Middle ear/Eustachian tube problems are the most common cause of isolated vertigo in children.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Tinnitus (PEDHD-16.5)

HDP.ED.0016.5.A
v2.0.2026

- Tinnitus without hearing loss is a less common complaint during childhood.
- Children with hearing loss and tinnitus should be imaged according to **Hearing Loss (PEDHD-16.1)**. A pertinent evaluation including a detailed history, physical examination (including otoscopic examination), and age-appropriate audiology testing should be performed on any child with known or suspected tinnitus prior to considering advanced imaging.
- Advanced imaging is not medically necessary in the overwhelming majority of pediatric individuals with isolated tinnitus and normal hearing.

Indications	Medically Necessary Imaging Study
• ANY of the following ◦ Clinical suspicion of mass lesion causing tinnitus ◦ Persistent tinnitus after recent significant trauma	• ONE of the following ◦ CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR** ◦ CT Orbits/Temporal Bone without and with contrast (CPT® 70482), **OR** ◦ MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) **OR** ◦ MRI Brain without contrast with attention to internal auditory canals (CPT® 70553) **OR** ◦ MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
• ANY of the following: ◦ Pulsatile tinnitus ◦ Suspicion for vascular lesions	• MRA Head (CPT® 70544, CPT® 70545 **OR** CPT® 70546) **OR** • CTA Head (CPT® 70496) **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548 **OR** CPT® 70549) **OR** • CTA Neck (CPT® 70498) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session.

Autism Spectrum Disorders (PEDHD-17.1)

HDP.AS.0017.1.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for:
  - new or worsening focal neurologic findings documented on a pertinent physical **AND/OR**
  - loss of developmental milestones and/or regression in two or more areas of development.
- PET imaging is considered not medically necessary in the evaluation of individuals with autism spectrum disorders.

Background and Supporting Information

- The group of diagnoses are classified as pervasive development disorders (PDD). These diagnoses are established on clinical criteria, and no imaging study can confirm the diagnosis.
- Comprehensive evaluation for autism might include history, physical exam, audiology evaluation, speech, language, and communication assessment, cognitive and behavioral assessments, and academic assessment.

Behavioral and Psychiatric Disorders (PEDHD-18.1)

HDP.BD.0018.1.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) **OR** CT Head without contrast (CPT® 70450) is medically necessary for:
  - acute onset mental status change.
  - new or worsening focal neurologic findings.
  - presentation of acute psychiatric symptoms with comorbid serious medical illness.
  - non-auditory hallucinations (e.g., visual, tactile, olfactory) with no known etiology.
  - non-response to adequate medication trials.
  - symptoms of an organic brain disorder (e.g., focal deficits, severe headache, or seizures).
- For concerns of PANS (Pediatric acute-onset neuropsychiatric syndrome) and PANDAS (Pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection), see **Movement Disorders including Tourette Syndrome (PEDHD-26)**.

Background and Supporting Information

- Routine brain imaging is not routinely recommended for obsessive compulsive disorder (OCD), attention deficit hyperactivity disorder (ADHD), and autism spectrum disorder (ASD).

Intellectual Disability (PEDHD-19.1)

HDP.ID.0019.1.A

v2.0.2026

- Intellectual disability may be primary or secondary to a variety of heterogeneous disorders. See **Background and Supporting Information**.
- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for new or worsening focal neurologic findings and/or new or worsening cognitive decline.

Background and Supporting Information

- Intellectual disability is a condition characterized by significant limitations in both intellectual functioning and adaptive behavior that originates before the age of 22. One way to measure intellectual functioning is an IQ test. Generally, an IQ test score of around 70 or as high as 75 indicates a significant limitation in intellectual functioning.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Cerebral Palsy (PEDHD-19.2)

HDP.ID.0019.2.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for:
  - initial evaluation of newly diagnosed cerebral palsy.
  - new or worsening focal neurologic findings documented on a physical examination, including the presence of developmental delay.
  - re-evaluation after 24 months of age due to rapid myelination during the first 2 years of life.
- For spinal imaging requests, see **Myelopathy (SP-7.1)** in the Spine Imaging Guidelines.

Background and Supporting Information

- Many individuals with intellectual disability also have cerebral palsy, but not all individuals with cerebral palsy have intellectual disability.
- Cerebral palsy is a static motor encephalopathy caused by a variety of entities spanning developmental, metabolic, genetic, infectious, ischemic, and other acquired etiologies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Developmental Motor Delay (PEDHD-19.3)

HDP.ID.0019.3.A

v2.0.2026

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for:
  - initial evaluation of newly diagnosed developmental motor delay with abnormal muscle tone.
  - toe walking, when associated with upper motor neuron signs including hyperreflexia, abnormal tone (spasticity/hypotonia), or positive Babinski sign.
  - new or worsening focal neurologic findings.
  - repeat brain imaging one time after 24 months of age due to rapid myelination during the first 2 years of life.
- For spinal imaging requests, see **Myelopathy (SP-7.1)** in the Spine Imaging Guidelines and **Spinal Dysraphism and Tethered Spinal Cord (PEDSP-4)** in the Pediatric and Special Populations Spine Imaging Guidelines.

Background and Supporting information

- There are many causes for developmental motor delay. Individuals with motor delay can have decreased, normal, or increased muscular tone. Individuals with normal tone do not require imaging unless they have focal neurologic findings.

Ataxia (PEDHD-20.1)

HDP.AT.0020.1.A
v2.0.2026

- See also **Developmental Disorders (PEDHD-19)**.
- A pertinent evaluation, including a detailed history and physical examination with a thorough neurologic examination, should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled follow-up imaging evaluation or request is from or in consultation with a neurologist or neurosurgeon who has seen the individual since onset of symptoms.

Indications	Medically Necessary Imaging Study
• ANY of the following: ◦ Ataxia ◦ Hereditary ataxia ◦ Slowly progressive ataxia	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **OR** • CT Head without contrast (CPT® 70450) *If the initial CT or MRI study is unable to answer the clinical question at hand, an exam of the other modality is medically necessary if needed to direct clinical management.*
• Suspected spinal etiology	• MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR** • MRI Lumbar Spine without contrast (CPT® 72148) **OR** • MRI Lumbar Spine without and with contrast (CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indications	Medically Necessary Imaging Study
• Acute ataxia following significant head trauma	• CT Head without contrast (CPT® 70450) **OR** • CT Head without and with contrast (CPT® 70470) **OR** • MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553)
• Contraindication to MRI	• CT Head without and with contrast (CPT® 70470) **OR** • CT Head with contrast (CPT® 70460
• BOTH of the following: ◦ Contraindication to MRI ◦ Suspected spinal etiology	• CT Cervical Spine without contrast (CPT® 72125) **OR** • CT Cervical Spine without and with contrast (CPT® 72127) **AND/OR** • CT Thoracic Spine without contrast (CPT® 72128) **OR** • CT Thoracic Spine without and with contrast (CPT® 72130) **AND/OR** • CT Lumbar Spine without contrast (CPT® 72131) **OR** • CT Lumbar Spine without and with contrast (CPT® 72133)

- Repeat imaging is medically necessary when ordered by a neurologist or neurosurgeon, or any provider in consultation with one of these providers, or if there are new signs or symptoms.

Background and Supporting Information

- Ataxia refers to an abnormally ill-coordinated or unsteady gait for age. "Limb ataxia" refers to impaired coordination (for age) of limbs, especially arms. Developmental failure to acquire the ability to walk is a form of developmental delay, not ataxia.
- CT should not be used in place of MRI solely to avoid sedation in young children because MRI is superior for imaging the posterior fossa.

Epistaxis Imaging (PEDHD-21.1)

HDP.ET.0021.1.A

v2.0.2026

- Initial evaluation of epistaxis (nosebleed), including recurrent epistaxis that is refractory to medical management is by direct or endoscopic visualization of the relevant portions of the upper airway.
- If a mass lesion is detected on direct visualization, the following imaging studies are medically necessary:
  - CT Maxillofacial without contrast (CPT® 70486) **OR** CT Maxillofacial without and with contrast (CPT® 70488) **AND/OR**
  - MRI Orbits/Face/Neck without and with contrast (CPT® 70543)

Pediatric Sleep Disorders (PEDHD-24.1)

HDP.SD.0024.1.A

v2.0.2026

- See **Pediatric Sleep Guidelines (SL-3)** in the Sleep Apnea and Treatment Clinical Guidelines.
- For over 18 years of age OR regarding oral appliance OR hypersomnolence, see **Sleep-Related Imaging Guidelines (HD-37)** in the Head Imaging Guidelines.
- For Obstructive Sleep Apnea:
  - Imaging prior to tonsillectomy (with or without adenoidectomy) for obstructive sleep apnea is not medically necessary.
  - Initially, endoscopic examination of the upper airway should be performed.
    - CT Maxillofacial without contrast (CPT® 70486) is medically necessary for evaluation of obstructive anatomy if operative intervention, other than a tonsillectomy (with or without adenoidectomy), is being considered.
- For suspected central sleep apnea, the following is medically necessary:
  - MRI Brain without contrast (CPT® 70551) OR
  - MRI Brain without and with contrast (CPT® 70553)
- Advanced imaging is NOT medically necessary for the following:
  - Confusional arousals
  - Sleep terrors
  - Nightmare disorder
  - Sleepwalking (somnambulism)
  - Bed wetting (enuresis)
  - Insomnia
  - Narcolepsy (without or with cataplexy)
  - Restless leg syndrome/periodic limb movement disorder
- For suspected sleep-related seizure imaging, see **Epilepsy and Other Seizure Disorders (PEDHD-6)**.

Temporomandibular Joint Imaging (PEDHD-25.1)

HDP.TJ.0025.1.A

v2.0.2026

- Temporomandibular Joint (TMJ) imaging indications in pediatric individuals are very similar to those for adult individuals. See **Temporomandibular Joint Disease (TMJ) (HD-30.1)** in the Head Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - There is a paucity of clinical symptoms and poor sensitivity of conventional x-rays in diagnosing TMJ arthritis in pediatric individuals with arthritis.
- MRI TMJ (CPT® 70336) is medically necessary annually for detecting silent TMJ arthritis in children with juvenile idiopathic arthritis (JIA) as requested by a rheumatologist and/or oral/maxillofacial surgeon (OMS) and/or any provider in consultation with a rheumatologist or OMS.
- Repeat imaging with MRI TMJ (CPT® 70336) in individuals with JIA is medically necessary for any of the following:
  - Change in signs or symptoms suggesting progression of disease
  - To monitor the effects of treatment
- Bone Scintigraphy/Bone Scan 3 Phase Study (CPT® 78315) in individuals over 12 years of age is medically necessary in anticipation or consideration of surgery.
- Unilateral condylar hyperplasia is manifested by slow growth in areas of the mandible causing facial asymmetry. It is usually a self-limiting condition seen predominantly in 12-30 year-olds.

Tourette Syndrome (PEDHD-26.1)

HDP.MD.0026.1.A

v2.0.2026

- The diagnosis of Tourette syndrome is made clinically and advanced neuroimaging is not medically necessary for either diagnosis or management.

Background and Supporting Information

- Tourette syndrome (TS) is a neurological disorder characterized by repetitive, stereotyped, involuntary movements and vocalizations called tics. The first symptoms of TS are almost always noticed in childhood. Some of the more common tics include eye blinking and other vision irregularities, facial grimacing, shoulder shrugging, and head or shoulder jerking. Perhaps the most dramatic and disabling tics are those that result in self-harm such as punching oneself in the face, or vocal tics including coprolalia (uttering swear words) or echolalia (repeating the words or phrases of others). Many with TS experience additional neurobehavioral problems including inattention, hyperactivity and impulsivity, and obsessive-compulsive symptoms such as intrusive thoughts/worries and repetitive behaviors.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Movement Disorders (PEDHD-26.2)

HDP.MD.0026.2.A

v2.0.2026

- MRI Brain without contrast (CPT® 70551), **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary in the following clinical scenarios:
  - Atypical clinical features for example, movements that persist in sleep, onset outside of typical age at onset (4-6 years for tics), rapid progression, incomplete or uncertain medication responsiveness, clinical diagnostic uncertainty, limbic encephalitis
  - Dystonia, intermittent involuntary muscle contractions
  - Chorea, continual irregular movements
  - Ballism, involuntary high amplitude movements
  - Athetosis, slow writhing continuous movements
  - Myoclonus, involuntary muscle jerks (not sleep myoclonus)
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary only after a complete medical workup including labs, acute infection, and other comorbid psychiatric disorders (examples, such as obsessive compulsive disorder (OCD), attention deficit hyperactivity disorder (ADHD), and autism spectrum disorder (ASD) have been investigated for concerns of:
  - PANS (pediatric acute-onset neuropsychiatric syndrome) **AND/OR**
  - PANDAS (pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection)
- See **Movement Disorders (HD-15.1)** in the Head Imaging Guidelines for the following:
  - Suspected Huntington disease
  - Evaluation for surgical treatment of essential tremor or Parkinson's disease, including deep brain stimulator (DBS) placement

Background and Supporting Information

- Movement disorders are hyperkinetic and hypokinetic movements that are involuntary. The majority are diagnosed based on a clinical diagnosis and do not require imaging.
- Typically, benign movement disorders include:
  - Stereotypies, repetitive rhythmic movements
  - Tics that are vocal or motor with typical onset and course
  - Tourette syndrome
  - Essential tremor or tremors of anxiety or weakness
  - Restless leg syndrome

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Routine brain imaging is not routinely recommended for OCD, ADHD, or ASD.
- There is little evidence to support the use of MRA/CTA and PET in the evaluation of movement disorders.

Proprietary Information of UnitedHealthcare.

CNS Infection (PEDHD-29.1)

HDP.CI.0029.1.A

v2.0.2026

- CNS infection imaging indications in pediatric individuals are similar to those for adult individuals. See **CNS and Head Infection (HD-14.1)** in the Head Imaging Guidelines.
- For COVID-19 infection, see **Neuro-COVID-19 and Sars-CoV-2 Vaccines (HD 14.2)** in the Head Imaging Guidelines.
- For Multisystem Inflammatory Syndrome in Children (MIS-C), see **COVID-19 and Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDHD-12.7)**.
- For autoimmune/paraneoplastic encephalitis, see **Autoimmune/Paraneoplastic Encephalitis & Neuroinflammatory Disorders (HD-14.3)** in the Head Imaging Guidelines.
- For pediatric-specific imaging considerations, including suspected congenital brain infection and neonatal meningitis, the following is medically necessary:
  - Ultrasound Head (CPT© 76506) **AND/OR**
  - CT Head without contrast (CPT® 70450) **OR** CT Head without and with contrast (CPT® 70470)

    AND/OR
  - MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551)
- Newborn infants with microcephaly should be evaluated as discussed in **Macrocephaly, Microcephaly, and Hydrocephalus (PEDHD-7).**

Background and Supporting Information

- Neonatal meningitis most often is caused by bacterial pathogens and usually occurs as a complication of sepsis in the first week of life. In older infants and children, meningeal inoculation occurs secondary to hematogenous spread or penetrating trauma.
- The common causes of prenatal infections of the central nervous system are cytomegalovirus, *Toxoplasma gondii*, herpes simplex type 2 virus, and most recently, zika virus. The findings suggesting prenatal brain infection include microcephaly, microphthalmia, chorioretinitis, cataracts, hypotonia, and seizures.

HDP.SL.0030.1.A
v2.0.2026

- Scalp and skull lesion imaging indications (including Pott Puffy Tumor) in pediatric individuals are identical to those for adult individuals with the exception of neonates. See **Scalp and Skull Lesions (HD-20.1)** in the Head Imaging Guidelines.
- For neonates with palpable scalp and skull lesions, the following is medically necessary:
  - Ultrasound Head (CPT® 76506) **AND/OR**
  - MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - CT Head without and with contrast (CPT® 70470)

Background and Supporting Information

- In neonates and young infants, scalp masses include the following:
  - Congenital lesions (cephalocele, dermoid cyst, epidermoid cyst)
  - Vascular lesions (hemangioma, sinus pericranii)
  - Extracranial hemorrhage related to birth trauma (caput succedaneum, cephalohematoma, subgaleal hematoma)
  - After the first year of life, malignant tumors, such as Langerhans cell histiocytosis, as well as metastases from neuroblastoma and rhabdomyosarcoma are additional causes of a scalp mass.

Eye Disorders (PEDHD-31.1)

HDP.EY.0031.1.A
v2.0.2026

- Eye disorder imaging indications in pediatric individuals are close to identical to those for adult individuals. See **Eye Disorders and Visual Loss (HD-32.1)** in the Head Imaging Guidelines.

Indication	Medically Necessary Imaging Study
◦ Evaluation for congenital disorders or disorders that begin early in life, such as, but not limited to the following: ▪ Optic nerve hypoplasia ▪ Septo-optic dysplasia ▪ Infantile nystagmus syndrome	◦ MRI Orbits/Face/Neck without contrast (CPT® 70540) **OR** ◦ MRI Orbits/Face/Neck without and with contrast (CPT® 70543) **OR** ◦ CT Orbits/Temporal Bone with contrast (CPT® 70481) **OR** ◦ CT Orbits/Temporal Bone without contrast (CPT® 70480) **AND/OR** ◦ MRI Brain without contrast (CPT® 70551) **OR** ◦ MRI Brain without and with contrast (CPT® 70553)

- Repeat imaging is medically necessary if requested by a neurologist, ophthalmologist, neuro-ophthalmologist, or neurosurgeon, or in consultation with one of these providers.
- For traumatic retinal hemorrhages as seen in suspected shaken baby syndrome, see **Head Trauma (PEDHD-4.1)**.
- For suspected and/or confirmed neuroblastoma, see **Neuroblastoma (PEDONC-6)**.
- For orbital cellulitis, see **Eye Disorders and Visual Loss (HD-32.1)** and/or **Imaging in Sinusitis (PEDHD-5.2)**.

Background and Supporting Information

- Neuroblastoma may be suspected in the setting of disorders, such as, but not limited to, Opsoclonus-Myoclonus syndrome, Horner's syndrome, and/or choroidal metastases.

General Guidelines (PEDMS-1.0)

MSP.GG.0001.0.A

v2.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination, appropriate laboratory studies and basic imaging such as plain x-ray or ultrasound should be performed prior to considering advanced imaging (CT, MR, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) can serve as a pertinent clinical evaluation.
- Plain x-ray should be done prior to advanced imaging. The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider of the advanced imaging study. X-ray can rule out those situations that do not require advanced imaging, such as acute/healing fracture, osteomyelitis, and tumors of bone amenable to biopsy or radiation therapy (in known metastatic disease), etc.
  - Even in soft tissue masses, plain x-rays are helpful in evaluating for calcium/bony deposits, e.g. myositis ossificans and invasion of bone.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the same body area are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.
- Provider-directed conservative care may include any or all of the following: R.I.C.E (rest, ice, compression, and elevation), NSAIDs (non-steroidal anti-inflammatory drugs), narcotic and non-narcotic analgesic medications, oral or injectable corticosteroids, viscosupplementation injections, a provider-directed home exercise program, cross-training, physical medicine, or immobilization by splinting/casting/bracing.
- These guidelines are based upon using advanced imaging to answer specific clinical questions that will affect patient management. Imaging is not indicated if the results will not affect individual management decisions. Standard medical practice would dictate continuing conservative therapy prior to advanced imaging in individuals who are improving on current treatment programs.

Health Equity Consideration

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence;

Age Considerations (PEDMS-1.1)

MSP.GG.0001.1.A

v2.0.2026

- Many conditions affecting the musculoskeletal system in the pediatric population have different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals who are ≤18 years old should be imaged according to the Pediatric Musculoskeletal Imaging Guidelines if discussed. Any conditions not specifically discussed in the Pediatric Musculoskeletal Imaging Guidelines should be imaged according to the General Musculoskeletal Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Musculoskeletal Imaging Guidelines except where directed otherwise by a specific guideline section.

Proprietary Information of UnitedHealthcare.

Appropriate Clinical Evaluation and Conservative Treatment (PEDMS-1.2)

MSP.GG.0001.2.A
v2.0.2026

- See: **General Guidelines (PEDMS-1.0)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Modality General Considerations (PEDMS-1.3)

MSP.GG.0001.3.A
v2.0.2026

- MRI
  - MRI without contrast is the preferred modality for pediatric musculoskeletal imaging unless otherwise stated in a specific guideline section, as it is superior in imaging the soft tissues and can also define physiological processes in some instances, e.g. edema, loss of circulation (AVN), and increased vascularity (tumors).
  - MRI without and with contrast is frequently recommended for evaluation of tumors, infection, post-operative evaluation, arthrography, and juvenile idiopathic arthritis, as described in the disease-specific guideline sections.
  - Due to the length of time required for MRI acquisition and the need to minimize movement, anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years), as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous route. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If multiple body areas are supported by these guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same imaging session.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - The presence of surgical hardware or implanted devices may preclude MRI, as magnetic field distortion may limit detail in adjacent structures. CT may be the procedure of choice in these cases.
  - The selection of best examination may require coordination between the provider and the imaging service.
- CT
  - CT without contrast is generally superior to MRI for imaging bone and joint anatomy; thus it is useful for studying complex fractures (particularly of the joints, dislocations, and assessing delayed union or non-union of fractures, integration of bone graft material, if plain x-rays are equivocal.
    - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
  - CT beam attenuation can result in streak artifact which can obscure adjacent details. This can occur with radiopaque material such as metal objects or dense bones.
  - The selection of best examination may require coordination between the requesting provider and the rendering imaging facility.
- Ultrasound
  - Ultrasound is frequently used to evaluate infants for hip dysplasia, to detect and/or aspirate joint effusion, and as an initial evaluation of extremity soft tissue masses.
  - CPT® codes vary by body area and the use of Doppler imaging. These CPT® codes are included in the table at the beginning of this guideline.
- Nuclear Medicine
  - Nuclear medicine studies are commonly used in evaluation of the peripheral musculoskeletal system, and other rare indications exist as well:
    - Bone scan (CPT® 78315), Distribution of Radiopharmaceutical Agent SPECT (CPT® 78803, or 78831), or SPECT/CT (CPT® 78830) is indicated for evaluation of suspected loosening of orthopedic prostheses when recent plain x-ray is nondiagnostic.
    - Nuclear medicine bone marrow imaging (CPT® codes: CPT® 78102, CPT® 78103, or CPT® 78104), SPECT (CPT® code: 78803), or SPECT/CT (CPT® 78830) is indicated for detection of ischemic or infarcted regions in sickle cell disease.
    - Triple phase bone scan (CPT® 78315) is indicated for evaluation of complex regional pain syndrome or reflex sympathetic dystrophy.
- 3D Rendering
  - 3D Rendering indications in pediatric musculoskeletal imaging are identical to those in the general imaging guidelines. See: **3D Rendering (MS-3)** for imaging guidelines.
- Bilateral Imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Coding for bilateral imaging may vary from health care plan to health care plan. Not all coding options may be available for all health care plans.

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Fracture and Dislocation (PEDMS-2)

MSP.FX.0002.0.A

v2.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination, and plain x-ray should be performed prior to considering advanced imaging.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Acute Fracture (PEDMS-2.1)

MSP.FX.0002.1.A

v2.0.2026

- Plain x-rays should be performed initially in any obvious or suspected acute fracture or dislocation.
  - If plain x-rays are positive, no further imaging is medically necessary except in complex (comminuted or displaced) joint fractures where MRI or CT without contrast is medically necessary for preoperative planning.
  - 3D Rendering may sometimes be medically necessary for complex fracture repairs. See: **3D Rendering (MS-3)** in the Musculoskeletal Imaging Guidelines.
- Ultrasound (CPT® 76881 or CPT® 76882) is medically necessary for evaluation of fracture, but is not required to allow for other advanced imaging, especially in infants. Ultrasound is typically a secondary method of fracture detection when used, though some centers use it as the sole imaging modality for skull and clavicle fractures.
- CT or MRI without contrast is medically necessary if plain x-rays are negative or equivocal for fracture, and fracture or bone marrow edema is still clinically suspected, and if the results will determine immediate treatment decisions as documented by the treating physician.
- Bone scan is medically necessary for evaluation of suspected fracture when two x-rays are negative at least 10 days apart, using any of the following CPT® code combinations:
  - CPT® 78300, CPT® 78305, or CPT® 78306 as a single study
  - See: **Stress/Occult Fracture (PEDMS-2.5)** for bone scan indications

Click Here to Return to the Main TOC

Joint-Adjacent Fracture (PEDMS-2.2)

MSP.FX.0002.2.A

v2.0.2026

- CT without contrast is medically necessary in complex (comminuted or displaced) fractures seen on plain x-ray involving a joint for preoperative planning.
- CT without contrast is medically necessary when there is clinical concern for delayed union or non-union of fracture or joint fusions on follow-up plain x-ray.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Growth Plate Injuries (Salter-Harris Fractures) (PEDMS-2.3)

MSP.FX.0002.3.A

v2.0.2026

- These fractures can generally be diagnosed and managed adequately with plain x-ray.
- In case of severe injury with displacement of bone fractures seen on plain x-ray, CT without contrast is medically necessary prior to surgical intervention.
- If there is concern for delayed union or non-union of the bone seen on plain x-ray, CT without contrast is medically necessary.
- MRI without contrast is medically necessary for the evaluation of a suspected physeal bar in a healing fracture or other complication of a fracture involving the growth plate seen on plain x-ray or CT which may result in abnormal growth. While physeal bars may be seen on CT, some fibrous physeal bars can be missed on CT. As such, MRI is the preferred imaging modality.
- Compressive injuries of the growth plate (Salter-Harris V) injuries may be difficult to identify on plain films, and MRI without contrast is medically necessary for confirmation.

Osteochondral or Chondral Fractures, Including Osteochondritis Dissecans (PEDMS-2.4)

MSP.FX.0002.4.A

v2.0.2026

An osteochondral fracture is a tear of the cartilage which covers the end of a bone, within a joint. It is also known as Osteochondritis Dissecans. In both disorders, the osteochondral fragment may separate from the articular surface and form loose bone fragments in a joint.

- If x-rays are negative and an osteochondral fracture is still suspected, or if x-ray or clinical exam suggests an unstable osteochondral injury, either MRI without contrast, MR arthrogram, or CT arthrogram of the involved joint is medically necessary.
- If plain x-rays show a non-displaced osteochondral fragment, follow up imaging should be with plain x-rays. Advanced imaging is not medically necessary.
- MRI without contrast or CT without contrast is medically necessary when healing cannot be adequately assessed on follow up plain x-rays.

Stress/Occult Fracture (PEDMS-2.5)

MSP.FX.0002.5.A

v2.0.2026

- These fractures can usually be adequately evaluated by history, physical exam, and x-ray. Advanced imaging may be medically necessary as discussed below if the initial evaluation of history, physical exam, and plain x-ray fails to establish a definitive diagnosis.
- Plain x-rays should be performed before advanced imaging. Plain x-rays are often negative initially, but may become positive after 14 days.
- If stress or occult fracture is suspected involving the pelvis, sacrum, hip, femur, tibia, tarsal navicular, proximal 5th metatarsal, or scaphoid, and initial plain x-ray fails to establish a definitive diagnosis:
  - MRI or CT without contrast is medically necessary, without conservative care or follow-up plain x-rays OR
  - Bone scan (CPT® 78315, 78306, or 78300), SPECT/CT (CPT® 78830), or Distribution Of Radiopharmaceutical Agent SPECT (CPT® 78803) is medically necessary in place of MRI or CT if provider requests
- For all other suspected stress or occult fractures, if follow-up plain x-rays are negative after 10 days of conservative care, or initial non-diagnostic x-ray is obtained a minimum of 14 days after the onset of symptoms:
  - MRI or CT without contrast is medically necessary OR
  - Bone scan (CPT® 78315, 78306, or 78300), SPECT/CT (CPT® 78830), or Distribution Of Radiopharmaceutical Agent SPECT (CPT® 78803) is medically necessary in place of MRI or CT if provider requests
- Periodic follow-up plain x-rays will usually show progressive healing.
  - CT without contrast is medically necessary when there is clinical concern for non-union.

Evidence Discussion (PEDMS-2)

v2.0.2026

Diagnostic imaging plays a critical role in the evaluation and management of pediatric fractures. Initial imaging with plain radiographs remains the standard for suspected fractures and stress reactions in children, as recommended by the American College of Radiology (ACR).[1] When radiographs are inconclusive or negative but clinical suspicion persists, advanced imaging modalities such as MRI and CT are considered appropriate next steps. MRI is highly sensitive and specific for detecting stress fractures and physeal injuries, especially when radiographs are inconclusive.[2-4] CT can be useful in assessing cortical bone detail but it involves exposing an individual to ionizing radiation, which may not be recommended in pediatric populations.[5,6] Ultrasound has been shown to be effective in detecting fractures in infants and young children, making it an option that avoids exposure to radiation and/or sedation.[7,8]

The risks of potential harm or adverse effects on pediatric individuals during imaging should be considered. MRI, while highly sensitive and specific, may require sedation in younger children which introduces anesthesia-related risks.[3,9] CT and bones scans additionally expose children to ionizing radiation, which could carry long term consequences.[5,10] Ultrasound is generally safe, non-invasive and radiation free; however, it is operator-dependent and diagnostic accuracy can be variable.[7,8]

It has been recommended that special consideration be given to imaging of growth plate and overuse injuries in children. Growth plate injuries require careful imaging assessment due to the potential for long-term growth disturbances. MRI is preferred for detailed evaluation of the growth plate and surrounding structure.[9,11] Physeal injuries, often resulting from sports or trauma, are best evaluated initially with radiographs. MRI is the preferred modality for assessing cartilage integrity and subchondral bone involvement, aiding in treatment planning and prognosis.[11,12]

Soft Tissue and Bone Masses – General Considerations (PEDMS-3.1)

MSP.ST.0003.1.A
v2.0.2026

- A pertinent clinical evaluation including a detailed history and physical examination should be performed prior to considering advanced imaging.
  - History and physical exam of any palpable soft tissue mass should include documentation of any of the following pertinent clinical features: location, size, and any association with pain.
- Plain x-rays should be performed as initial imaging. This is true even for soft tissue masses that are clearly not directly associated with osseous structures. Details such as soft tissue calcification, presence or absence of phleboliths, radiographic density, and any effect on adjacent bone are all potentially significant plain film findings that may help better identify the etiology of the mass and determine the optimal modality and contrast level when advanced imaging is indicated.
- Evaluation by a surgical specialist or oncologist is strongly recommended to help determine the most helpful advanced imaging studies for an individual.
- Ultrasound (CPT® 76881 or CPT® 76882) is medically necessary if initial plain x-ray is negative to evaluate:
  - ill-defined masses or areas of swelling
  - hematomas
  - subcutaneous lipomas with inconclusive clinical examination
  - lipomas in other locations
  - masses that have been present and stable for up to, or more than, 1 year
  - vascular malformations (see: **Vascular Anomalies (PEDPVD-2)** in the Pediatric Peripheral Vascular Disease Imaging Guidelines)
- MRI without and with contrast or without contrast is medically necessary for any of the following:
  - soft tissue mass greater than 5 cm in diameter
  - soft tissue mass increasing in size
  - painful soft tissue mass
  - deep soft tissue mass or subfascial location
- Advanced imaging is not medically necessary for the following entities:
  - ganglion cysts
  - sebaceous cysts
  - hematomas
  - subcutaneous lipomas
    - MRI without or without and with contrast can be performed if surgery is planned.

Proprietary Information of UnitedHealthcare.

Mass Involving Bone (Including Suspected Lytic and Blastic Metastatic Disease) (PEDMS-3.4)

MSP.ST.0003.4.A

v2.0.2026

- Plain x-rays of the entire bone containing the lesion are required prior to consideration of advanced imaging. Many benign bone tumors have a characteristic appearance on plain x-ray and advanced imaging is not medically necessary unless one of the following applies:
  - MRI without and with contrast and/or CT without is medically necessary for preoperative planning.
  - MRI without and with contrast is medically necessary when the diagnosis is uncertain based on plain x-ray appearance.
    - CT without or with contrast is medically necessary if MRI is contraindicated.
- Surveillance of benign bony lesions is with plain x-ray
  - MRI without and with contrast is medically necessary for new findings on x-ray, or new or worsening clinical symptoms not explained by recent x-ray.
- Osteochondroma, osteoid osteoma, osteogenic sarcoma, and Ewing sarcoma family of tumors should be imaged according to **Bone Tumors (PEDONC-9)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- If there is concern for metastatic disease in an individual with a known malignancy, refer to the appropriate Pediatric and Special Populations Oncology Imaging Guideline.

Evidence Discussion (PEDMS-3)

v2.0.2026

Diagnostic imaging plays a critical role in evaluating soft and bony tissue masses in pediatric patients. The American College of Radiology (ACR) recommends radiography as the initial imaging modality for suspected soft tissue and bone masses in children, as it provides essential information with minimal radiation exposure.[1,2] Radiographs can often identify benign lesions and guide further imaging decisions, reducing the need for advanced modalities when not clinically indicated.

For superficial soft tissue masses, ultrasound (US) is highly recommended as an imaging tool. It is non-invasive, free of ionizing radiation, and has demonstrated high sensitivity and specificity in characterizing superficial lesions in pediatric populations.[3-5] US can effectively differentiate cystic from solid masses and guide clinical management, including decisions regarding biopsy or surgical intervention. However, MRI may be necessary for preoperative planning or when deeper anatomical involvement is suspected.[1,6]

When radiographs are inconclusive or when malignancy is suspected, (MRI) without and with intravenous contrast is considered an appropriate next step. MRI offers superior soft tissue contrast and multiplanar capabilities, which are particularly valuable in pediatric patients due to their smaller anatomical structures and the need to avoid ionizing radiation.[1,2,5,7] However, MRI may require the use of sedation which could introduce anesthesia-related risks to consider.[1] CT may be used when MRI is contraindicated, but its use should be judicious given the increased sensitivity of children to radiation.

Health equity considerations are essential in pediatric imaging. Children from underserved communities may face barriers to accessing advanced imaging modalities.[9] Evidence supports the use of US and radiography as cost-effective and accessible options that maintain diagnostic accuracy while minimizing risk. Ensuring equitable access to appropriate imaging is critical for timely diagnosis and treatment across diverse pediatric populations.

General Evaluation of the Limping Child (PEDMS-4.1)

MSP.LC.0004.1.A

v2.0.2026

- This guideline primarily applies to children under the age of 6 years. It may also be applied to older children with pre-existing conditions who may not be able to communicate, such as a child with severe intellectual disability. Many of these cases will be urgent, because of the risk of adverse outcomes in delay of diagnosis.
- A pertinent clinical evaluation, including a detailed history and physical examination, should be performed, which will help determine any indication for advanced imaging. Based on this clinical evaluation, the most likely etiology should be determined, usually trauma, infection, or neither trauma nor infection.
- X-ray should be obtained if there are no localized findings on physical examination.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Limping Child with Suspected Trauma (PEDMS-4.2)

MSP.LC.0004.2.A

v2.0.2026

- Plain x-rays are indicated for detection of fractures, destructive lesions, and avascular necrosis. For children under age 4 this may require x-rays of the entire leg from hip to foot. If clinical suspicion is high for “toddler fracture” imaging may start with tibia/fibula x-rays, and if a fracture is demonstrated, additional imaging may not be required.
- If initial x-rays are negative, but limping symptoms or avoidance of weight-bearing persist, follow-up x-rays in 7 to 10 days are indicated.
  - If plain films are negative and suspicion remains high for stress fractures or soft tissue injury, the following are medically necessary:
    - MRI without contrast of the affected body area OR
    - Radionuclide bone scan (CPT® 78300, CPT® 78305, CPT® 78306, or CPT® 78315), SPECT/CT (CPT® 78830), or SPECT (CPT® 78803) if implanted hardware or devices precluding MRI are present.
- CT use is limited in the evaluation of the limping child with suspected trauma.

Proprietary Information of UnitedHealthcare.

Limping Child with Suspected Infection (PEDMS-4.3)

MSP.LC.0004.3.A
v2.0.2026

- Pain localized to hip:
  - It is essential to exclude septic arthritis. Ultrasound of the hip (CPT® 76881 or 76882) is used to exclude hip joint effusion.
    - Hip joint fluid aspiration to distinguish infection from non-infectious etiologies If hip joint effusion is demonstrated.
    - Plain x-rays should be obtained if no hip joint effusion is demonstrated.
    - MRI without contrast (CPT® 73721) or without and with contrast (CPT® 73723) is medically necessary if plain films are not diagnostic.
- Pain localized distal to hip:
  - MRI without contrast or without and with contrast of the affected body part is medically necessary if plain x-rays are not diagnostic.
- Non-localized pain:
  - Plain x-rays of the spine, pelvis, and lower extremities may be necessary to localize the abnormality.
  - If plain x-ray is not diagnostic and suspicion for infection remains high, one of the following:
    - Whole-body bone scan (CPT® 78306) OR
    - SPECT (CPT® 78803) OR
    - SPECT/CT (CPT® 78830) OR
    - MRI without contrast or without and with contrast of the affected body area

Limping Child with No Evidence of Trauma or Infection (PEDMS-4.4)

MSP.LC.0004.4.A
v2.0.2026

- This differential diagnosis is quite broad.
  - Transient (or toxic) synovitis of the hip:
    - Ultrasound of the hip (CPT® 76881 or CPT® 76882) is the medically necessary initial exam.
      - Plain x-rays if no hip effusion is demonstrated.
      - Hip joint fluid aspiration is indicated if a hip joint effusion is demonstrated. This is usually performed with US guidance, though fluoroscopic guidance or blind aspiration may be required.
  - Avascular Necrosis, see: **Avascular Necrosis (AVN)/ Legg-Calvé-Perthes Disease (PEDMS-6)**
  - Juvenile Idiopathic Arthritis, see: **Juvenile Idiopathic Arthritis (PEDMS-10.1)**
  - Histiocytic Disorders, see: **Histiocytic Disorders (PEDONC-18)** in the Pediatric and Special Populations Oncology Imaging Guidelines
  - Neoplasm, see: **General Guidelines (PEDONC-1)**, **Pediatric Leukemias (PEDONC-3)**, **Neuroblastoma (PEDONC-6)**, **Pediatric Soft Tissue Sarcomas (PEDONC-8)**, or **Bone Tumors (PEDONC-9)** in the Pediatric and Special Populations Oncology Imaging Guidelines

Developmental Dysplasia of the Hip (PEDMS-5)

MSP.DZ.0005.A
v2.0.2026

Screening studies

- The routine use of ultrasound in screening neonates and infants without risk factors for developmental dysplasia of the hip (DDH) is not recommended by the American Academy of Pediatrics and the American Academy of Orthopedic Surgeons.
- Screening ultrasound (CPT® 76885 or CPT® 76886) is medically necessary for infants between 4 weeks of age and 4 months of age with one or more of the following risk factors:
  - Breech presentation
  - Family history of DDH
  - Abnormal hip exam (e.g., positive Ortolani or Barlow maneuvers, asymmetric thigh folds, shortening of the thigh observed on the dislocated side, limitation of hip abduction)
- For children between 4 and 6 months of age plain x-ray is the initial imaging modality as femoral head ossification is often seen on x-ray in normal individuals.
  - If x-ray is inconclusive, ultrasound (CPT® 76885 or CPT® 76886) is medically necessary.

Follow-Up/Diagnostic Studies

- Ultrasound is medically necessary earlier than 4 weeks of age in individuals with unstable/dislocated hip(s) undergoing abduction brace treatment.
- Follow-up hip ultrasound (CPT® 76885 or CPT® 76886) is medically necessary for the following:
  - Graf type IIA hip with an alpha angle (bony angle) between 50 to 59 degrees in a child less than 3 months of age and follow up hip ultrasound is requested to confirm normal development
  - Subluxation or dislocation was diagnosed on previous hip ultrasound using the dynamic Harke imaging method
  - Prior ultrasound demonstrates abnormal hip and treatment has been applied (such as a Pavlik harness or other device) to document effectiveness of treatment, to ensure the femoral head remains located in the acetabulum, or to identify treatment failure.
    - The usual interval for follow-up sonography is monthly, but earlier imaging is medically necessary for clinical suspicion of treatment failure, subluxation or dislocation of the hip.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI without and with contrast (CPT® 73723), MRI without contrast (CPT® 73721), or CT without contrast (CPT® 73700) is medically necessary to evaluate alignment following reduction. Children in casts or following surgery may require repeated advanced imaging to ensure the reduction remains satisfactory, or to assess incorporation of bone graft material.
- Hip ultrasound is NOT medically necessary for the following:
  - Infants older than 6 months of age as plain x-ray of the hips become more reliable due to femoral head ossification and should be used in infants over 6 months of age.
  - Type I, IIB, IIC, IID, and III hips diagnosed on a previous hip ultrasound using the Graf method. Type I hip is normal, and Type IIB, IIC, IID, and III will have imaging as directed by treating provider.
  - Plain x-ray of the hips should be performed rather than ultrasound if there is a clinical suspicion for teratogenic dysplasia.

Background and Supporting Information

- Developmental dysplasia of the hip (DDH) was formerly known as congenital dislocation of the hip. DDH includes a spectrum of abnormalities including abnormal acetabular shape (dysplasia) and malposition of the femoral head ranging from reducible subluxation to irreducible subluxation or dislocation of the femoral head. 60 to 80% of abnormalities are identified by physical exam, and more than 90% are identified by ultrasound. Treatment may involve placement in a Pavlik harness, casting, or surgery in extreme or refractory cases.
- Hip laxity is normal after birth and usually resolves spontaneously.
- There are two sonographic methods of evaluating the hip: the dynamic stress (Harcke) technique and the static (Graf) technique
- The overwhelming majority of Graf type IIA hips mature spontaneously but follow up may be required to ensure that maturation has occurred.

Evidence Discussion (PEDMS-5)

v2.0.2026

Imaging plays an important role in the evaluation and assessment of developmental dysplasia of the hip (DDH). In the American College of Radiology Appropriateness Criteria, American Academy of Pediatrics recommendations and the American Academy of Orthopedic Surgeons Guideline, it is recommended that ultrasound (US) is appropriate for initial screening, diagnostic and follow-up of infants between 4 week and 4 months of age with risk factors for DDH (e.g., breech presentation, family history, abnormal exam) or earlier than 4 weeks of age in individuals undergoing abduction brace treatment.[1-3] US has been demonstrated to have sensitivity and specificity above 90% for detecting hip instability in early infancy and does not introduce any radiation exposure.[1,2,4] Radiographs are recommended as initial imaging after 4-6 months of age, when femoral head ossification is able to be seen, providing improved diagnostic accuracy.[1,5]

MRI has been recommended for use to evaluate hip alignment following reduction. Post-reduction evaluation may require assessment of adjacent soft tissues and MRI would be the best modality for complete visualization.[1,4,6] The use of MRI avoids ionization radiation, but it may require sedation and/or contrast media which could introduce additional risks such as respiratory depression or allergic reaction.[6] In situations where MRI is contraindicated or not available, CT has been recommended as an alternative. Its use is often limited to special circumstances, however, due to radiation exposure.[1,5]

Access to advanced imaging may be limited in areas with reduced resources, such as rural and underserved communities. Delays in accessing advanced imaging can disproportionately affect those in these socioeconomic situations. This may lead to a greater reliance on radiographs and ultrasound in those with limited access to avoid delays in diagnosis and appropriate [2,5]

Osteonecrosis (PEDMS-6.2)

MSP.AN.0006.2.A

v2.0.2026

- Osteonecrosis can occur in a number of conditions, including during treatment for developmental dysplasia of the hip.
- Individuals with acute lymphoblastic leukemia, lymphoblastic lymphoma, or other conditions with recurrent exposure to high dose corticosteroids and known or suspected osteonecrosis should be imaged according to guidelines in: **Acute Lymphoblastic Leukemia (ALL) (PEDONC-3.2)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Known or suspected osteonecrosis in long-term cancer survivors should be imaged according to guidelines in: **Osteonecrosis in Long Term Cancer Survivors (PEDONC-19.4)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- X-ray is indicated as initial imaging study
- MRI either without contrast or without and with contrast is medically necessary in other individuals with concern for osteonecrosis and negative or inconclusive recent x-ray, if imaging results will change current individual management. Early phase of osteonecrosis may be seen on MR with normal x-ray findings.
  - CT scan without contrast is medically necessary for surgical planning.

Evidence Discussion (PEDMS-6)

v2.0.2026

Plain radiography remains the typical first-line imaging modality in children with hip or extremity pain and suspected avascular necrosis because of its broad availability and low cost. Radiographs can help exclude other causes of pain (e.g., fracture, slipped capital femoral epiphysis, tumor). When additional diagnostic investigation is needed, MRI is recommended for early detection of osteonecrosis and similar conditions in children due to superior sensitivity and lack of ionizing radiation.[1-3]

Computed tomography (CT) and nuclear medicine modalities (bone scintigraphy, SPECT) may have a role in diagnosing children when MRI is inconclusive or contraindicated, or when detailed assessment of subchondral bone, articular surface integrity, or collapse is needed. CT provides excellent visualization of the bony architecture and degree of structural compromise but involves ionizing radiation and is less preferred in a pediatric context unless structural detail will change management.[1,4,5] Ultrasound can be useful adjunctively (e.g., effusion detection, hip containment in Legg-Calve-Perthes Disease) but has limited sensitivity and specificity for early ON/AVN.[6]

MRI is recommended to evaluate suspicion of Legg-Calve-Perthes Disease. Especially during the early stages of clinical evaluation and diagnosis. Early on, radiographs alone may be insufficient to display structural changes around the femoral head and could lead to a delay in diagnosis.[6] MRI has been shown to be most sensitive in visualizing early ischemic changes before radiographic findings are visible.[2,3]

MRI screening in pediatric oncology populations has demonstrated detection of subclinical lesions, enabling earlier surveillance and management.[5,7] The lack of ionizing radiation is particularly relevant in children who require repeated imaging during growth and long term follow up.[7-9] In children treated for risk factors such as high dose corticosteroids (e.g., in acute lymphoblastic leukemia), malignancy, bone marrow transplantation, or other bone/vascular insults, the literature supports that advanced imaging—particularly MRI—is more sensitive and specific for early ON/AVN prior to collapse of the epiphysis or femoral head.[7,8]

The risks of exposing pediatric individuals to harm should be a consideration during diagnostic imaging. MRI avoids exposure to ionizing radiation and is recommended over CT and bone scan when at all possible.[1,4,9,10] MRI may also allow for earlier detection of osteonecrosis/avascular necrosis before collapse when compared to CT or bone scan. Earlier detection could allow for improved outcomes including long-term joint preservation and reducing the need for surgical intervention.[6,10] It has also been recommended to weigh the benefits versus the risks in the use of sedation and contrast media when selecting an appropriate imaging modality. Complications such as respiratory compromise or allergic reaction could occur.[4] There may also be inequities in access to appropriate imaging which may require specific consideration. Pediatric ON/

AVN disproportionately affects adolescents, children treated in lower-socioeconomic settings, and survivors of childhood cancer; ensuring access to advanced imaging may mitigate disparities in joint salvage outcomes.[1,10,11]

Suspected Physical Child Abuse (PEDMS-7)

MSP.AB.0007.A
v2.0.2026

The suspicion of physical abuse of a child often requires imaging, both for clinical management and for forensic purposes. Every effort should be made to support reasonable requests for imaging in these children.

Child abuse injuries may affect any organ or system. Fractures are common, but injuries may also involve solid and hollow visceral organs, and/or superficial and deep soft tissue injuries. Some fracture patterns are highly correlated with non-accidental mechanisms, such as the classic metaphyseal lesion, also known as a corner fracture or bucket handle fracture, but fractures may occur in any bone. Unsuspected fractures, multiple fractures at various stages of healing, or fractures of a configuration or distribution inconsistent with the history provided, may raise the suspicion for physical abuse.

Skeletal Injury

- The x-ray skeletal survey is the primary imaging procedure for detecting fractures, especially in children age 24 months or younger. In older children, skeletal survey may be indicated, but more tailored x-ray evaluation based on history and physical examination may be preferable to skeletal survey.
- When skeletal survey is negative, but clinical suspicion remains high, either of the following are medically necessary:
  - Bone scan (CPT® codes: CPT® 78300, 78305, 78306, 78315, or 78830) OR
  - Distribution of Radiopharmaceutical Agent SPECT (CPT® 78803)
- Suspected injury to the spine should usually first be evaluated with plain x-rays. CT without contrast and/or MRI without contrast or without and with contrast may be required for complete evaluation of osseous and soft tissue spine injuries. If requested for suspected or known physical abuse, both CT without contrast and/or MRI without contrast or without and with contrast of suspected sites are medically necessary.
- CT Chest without contrast (CPT® 71250) is medically necessary in individuals with a negative skeletal survey and a high clinical suspicion for rib fracture associated with child abuse.
- A repeat skeletal survey performed approximately 2 weeks after the initial examination can provide additional information on the presence and age of child abuse fractures and should be performed when abnormal or equivocal findings are found on the initial study and when abuse is suspected on clinical grounds

Click Here to Return to the Main TOC

Head Injury

- CT Head without contrast (CPT® 70450) is medically necessary when there is clinical evidence of head injury or when skull fracture of any age is detected on survey skull x-ray.
  - CT Head without contrast (CPT® 70450) is also medically necessary when known or suspected cervical trauma is present in a pediatric individual.
  - CT Head without contrast (CPT® 70450) is medically necessary in individuals less than 1 year of age, even if no neurologic symptoms are detected due to the great potential morbidity of abuse head trauma. MRI Brain without contrast (CPT® 70551) is also medically necessary.
  - MRI Spine without contrast (CPT® 72141, 72146, 72148) or without and with contrast (CPT® 72156, 72157, 72158) is medically necessary when there is clinical evidence of head injury or when skull fracture of any age is detected on survey skull x-ray. CT Spine (CPT® 72125, CPT® 72128, CPT® 72131) is medically necessary if MRI is not readily available.
- MRI Brain without contrast (CPT® 70551) or without and with contrast (CPT® 70553) is medically necessary to evaluate brain parenchymal injury, or in a child where the clinical signs of brain injury are not sufficiently explained by CT findings.

Other Body Area Injuries

- CT should be performed with contrast unless an absolute contraindication exists.
- ANY of the following imaging studies are medically necessary for suspected injury to the abdomen or pelvis:
  - Abdominal ultrasound (CPT® 76700)
  - Pelvic ultrasound (CPT® 76856)
  - CT Abdomen with contrast (CPT® 74160)
  - CT Pelvis with contrast (CPT® 72193)
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
- ANY of the following imaging studies are medically necessary for suspected injury to the chest:
  - CT Chest without contrast (CPT® 71250)
  - CT Chest with contrast (CPT® 71260)

Screening of other children

- Contacts are defined as the asymptomatic siblings, cohabiting children, or children under the same care as an index child with suspected child physical abuse. All contact children should undergo a thorough physical examination and a history elicited prior to imaging. Contact children younger than 12 months should have neuroimaging, and skeletal survey. CT Head without contrast (CPT® 70450) or MRI Brain without contrast (CPT® 70551) is medically necessary. Contact children aged

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

12 to 24 months should undergo skeletal survey. No routine imaging is medically necessary in asymptomatic children older than 24 months.

Evidence Discussion (PEDMS-7)

v2.0.2026

Imaging for the evaluation of suspected physical abuse of a child is critical to both the success of clinical management and for forensic investigation. In children under 2 years of age, radiographic skeletal surveys are typically recommended as the cornerstone for detecting fractures in suspected abuse.[1-3] Skeletal surveys may still be helpful in older children, but when a more thorough history can be obtained, a tailored radiographic examination may be appropriate. When radiographic examinations are negative but clinical suspicion remains bone scan is recommended as it is useful in detecting subtle fractures.[1,2]

Radiographs may not always be sufficient in the examination of suspected physical abuse. MRI has been recommended, especially in suspected spine and head injury, and is preferred over CT in its ability to detect ligamentous and cord injury.[4-6] CT can be a helpful option to provide improved bony details in assessing head and spine injury or when MRI is contraindicated or unavailable.[1,7] When acute intracranial injury is suspected or skull fracture is detected on radiograph, CT of the head is recommended as a first-line imaging due to its speed and sensitivity.[1,5,7] Additionally, MRI of the spine is also recommended in cases of clinical evidence of head injury or detection of skull fracture to add diagnostic value beyond head imaging.[4,5] CT of the abdomen and pelvis, with contrast, is recommended when there is concern for visceral injury.[1,7,8] CT of the chest may also be of use as it can help detect rib fractures and other injury not evident on radiographs.[1,7]

When appropriate, MRI is recommended over CT or bone scan to eliminate risks associated with exposure to radiation. However, MRI may require sedation which presents other risks such as respiratory depression.[1,4,7,8] Acute traumatic cases, or individuals with limited access to imaging types, may be better served by the type of image that can provide a diagnosis in a timely manner to avoid harm due to delays in diagnosis.[3,5,6]

Infection/Osteomyelitis (PEDMS-8)

MSP.OI.0008.A
v2.0.2026

- Infection and osteomyelitis imaging indications in pediatric individuals are similar to those for adult individuals other than the limping child.
  - See: **General Infection/Osteomyelitis (MS-9.1)** and **Charcot and Septic Joint (MS-9.2)** in the Musculoskeletal Imaging Guidelines for circumstances other than in the limping child.
  - See: **Limping Child with Suspected Infection (PEDMS-4.3)** for imaging guidelines when limping is present.
  - See: **Inflammatory Musculoskeletal Disease (PEDMS-10)** for imaging guidelines for chronic recurrent multifocal osteomyelitis (CRMO, which is an autoimmune disease).
- Ultrasound of the involved extremity (CPT® 76881 or CPT® 76882) is medically necessary to evaluate for effusion or soft tissue fluid collection
  - Ultrasound is not a prerequisite for other advanced imaging studies
- Bone scan (CPT® 78300, 78305, 78306, or 78315), SPECT/CT (CPT® 78830, or 78832), or SPECT (CPT® 78803, or 78831) is medically necessary for evaluation of suspected bone infection if MRI cannot be done and when infection is multifocal, or when the infection is associated with orthopedic hardware or chronic bone alterations from trauma or surgery. Combining bone scintigraphy with a labeled leukocyte scan enhances sensitivity. A labeled leukocyte scan (radiopharmaceutical localization of tumor, inflammatory process, or distribution of radiopharmaceutical agent(s) imaging) - one of the following CPT® codes: CPT® 78800, CPT® 78801, 78802, or CPT® 78803 in concert with Tc-99m sulfur colloid marrow imaging (one of CPT® codes: CPT® 78102, CPT® 78103, or CPT® 78104) or SPECT/CT (CPT® 78830) is medically necessary in cases with altered bone marrow distribution, such as joint prosthesis.

Juvenile Idiopathic Arthritis (PEDMS-10.1)

MSP.MD.0010.1.A

v2.0.2026

- Ultrasound (CPT® 76881 or 76882) is medically necessary for assessment of: size and characteristics of joint effusions, extent of synovial hypertrophy (which is the hallmark of juvenile idiopathic arthritis), and involvement of tendinous structures.
  - Repeat imaging is medically necessary for monitoring treatment or with planned treatment change
  - MRI of the most symptomatic joint without contrast or without and with contrast is medically necessary if ultrasound is inconclusive and MRI findings would alter individual management
- Distribution of Radiopharmaceutical Agent SPECT (CPT® 78802, or 78803), or SPECT/CT (CPT® 78830), is medically necessary for evaluation of facet arthropathy in patients with ankylosing spondylitis, osteoarthritis, or rheumatoid arthritis.
- MRI TMJ (CPT® 70336) is medically necessary annually for detecting silent TMJ arthritis in children with juvenile idiopathic arthritis (JIA).
- MRI without or without and with of the most involved joint is medically necessary to evaluate involved or symptomatic joints in the following situations:
  - When diagnosis is uncertain prior to initiation of drug therapy
  - To study the effects of treatment with disease modifying anti-rheumatic drug (DMARD) therapy
  - To determine a change in treatment
- MRI (with the exception of the annual screening MRI of the TMJ discussed above) is not medically necessary for routine follow-up of treatment.

Chronic Recurrent Multifocal Osteomyelitis (PEDMS-10.2)

MSP.MD.0010.2.A
v2.0.2026

Chronic recurrent multifocal osteomyelitis (CRMO) is a rare autoimmune disease affecting multiple bones, arising most commonly during the second decade of life. Treatment consists of anti-inflammatory and immunomodulatory therapies, and is directed predominantly by status of clinical symptoms (most commonly pain).

- The following imaging is medically necessary for individuals with CRMO for evaluation of new or worsening pain, or response to treatment in individuals without complete clinical resolution of pain symptoms, when plain x-rays are non-diagnostic:
  - Bone scan (CPT® codes: 78300, 78305, 78306, 78315) OR
  - SPECT (CPT® codes: 78803, or 78831), OR
  - Nuclear Bone Marrow imaging (CPT® codes: 78102, 78103, or 78104), OR
  - Radiopharmaceutical localization of tumor, inflammatory process, or distribution of radiopharmaceutical agent imaging (CPT® codes: 78800, 78801, 78802, or 78803), OR
  - SPECT/CT (CPT® codes: 78830, or 78832)
  - MRI without contrast of specific painful body areas when plain x-ray and bone scan are insufficient to direct acute individual care decisions.
- Literature suggests MRI may have greater sensitivity for clinically occult lesions than bone scan. Whole-body MRI (CPT® 76498) is medically necessary for CRMO in the following situations:
  - Individuals suspected of having CRMO if characteristic MR findings of CRMO would preclude the need for a biopsy.
    - Characteristic finding include multiple lesions most commonly involving the juxtaphyseal/peri-physeal portions of the tibia and femur, the clavicle and thoracolumbar spine.
  - Every 6-12 months in individuals with an established diagnosis of CRMO to monitor treatment or to evaluate for clinically occult but radiographically active lesions.
  - See: **Whole Body MR Imaging (Preface-5.2)** for additional details.

Inflammatory Muscle Diseases (PEDMS-10.3)

MSP.MD.0010.3.A
v2.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination, and plain x-rays should be performed prior to considering advanced imaging.

Inflammatory Muscle Diseases:

These include but are not limited to dermatomyositis, polymyositis, and sporadic inclusion body myositis. MRI without contrast of a single site is medically necessary in these disorders for the following purposes:

- Selection of biopsy site
- Clinical concern for progression
- Treatment monitoring
- Detection of occult malignancy

Juvenile Dermatomyositis:

Contrary to adult dermatomyositis, juvenile dermatomyositis is very rarely paraneoplastic in nature, and routine screening for occult neoplasm is not medically necessary.

The following are medically necessary for juvenile dermatomyositis:

- MRI without contrast to confirm the diagnosis and thus avoid a biopsy.
- CT without contrast (CPT® 73700) or MRI (CPT® 73718) to follow progressive calcification in muscles
  - Both CT and MRI are rarely indicated concurrently.
- CT Chest (CPT® 71260) and Abdomen and Pelvis (CPT® 74177) with contrast for individuals with palpable lymphadenopathy or hepatosplenomegaly.

Evidence Discussion (PEDMS-10)

v2.0.2026

Imaging plays a critical role in the evaluation and management of pediatric inflammatory musculoskeletal diseases. Initial radiographs, along with a detailed history and physical examination, can help determine what advanced imaging may be needed. Guidelines recommend that imaging strategies be tailored to the clinical scenario to optimize diagnostic accuracy and safety.[1,2]

MRI and ultrasound (US) are recommended as first-line advanced imaging for juvenile idiopathic arthritis (JIA). US has been shown to be instrumental in detecting joint effusion and is recommended for the early detection synovial inflammation.[1,3,4] MRI, with sensitivity exceeding 90% in JIA, is recommended when US is inconclusive as it can provide comprehensive assessment of joint inflammation, bone marrow edema, and cartilage damage.[5,6] CT and scintigraphy are rarely recommended due to radiation exposure, but may be necessary in limited or atypical cases.[1]

Both bone scintigraphy and MRI are recommended for the diagnostic imaging of chronic recurrent multifocal osteomyelitis (CRMO). Scintigraphy can be helpful in the assessment of new or worsening pain and evaluating the response to treatments.[7] However, it has been shown to have lower sensitivity and specificity compared to MRI.[7] With sensitivity over 90% for lesion detection, whole-body MRI is recommended as the superior modality for detecting multifocal bone lesions and monitoring disease activity.[2,7-10] Additionally, MRI avoids ionizing radiation, making it safer for repeated imaging compared to CT or bone scans.[9]

MRI is also the recommended imaging modality to confirm diagnosis for juvenile muscle disease (e.g., dermatomyositis, polymyositis, inclusion body myositis). MRI is more sensitive to deep muscle edema and changes than US and may help to avoid unnecessary biopsy.[3,6] CT is not typically recommended for general diagnosis as it has limited use in soft tissue visualization and to avoid radiation exposure.[1] However, CT may be helpful in the assessment of muscle calcification or enlargement of abdominopelvic organs and/or lymph nodes.

Special consideration of potential risks to the individual from imaging must be made, especially in cases where monitoring through repeat images over time will be needed.[9] CT and bone scans involve ionizing radiation which can be harmful and should be avoided when possible.[1,9] While MRI does not expose an individual to radiation, younger individuals may require sedation for clear images to be obtained which can pose risks such respiratory depression.[5,11] There are also risks of allergic reactions to IV contrast. Additional consideration should be given to those with limited access to advanced imaging. Rural and limited resource areas may not provide easy access to the most appropriate imaging modality.[12] Alternatives may be recommended to avoid delays in appropriate care.

Evidence Discussion (PEDMS-12)

v2.0.2026

Osgood-Schlatter disease is a self-limiting condition that is secondary to repetitive stress of the knee extensor mechanism. It is recommended that clinical exam, history and X-rays are sufficient for diagnosis with high accuracy. Advanced imaging adds little diagnostic benefit, unnecessarily increases healthcare costs, and is generally not recommended.[1-4]

Popliteal (Baker) Cyst (PEDMS-13)

MSP.PC.0013.A
v2.0.2026

Popliteal or Baker cyst in children is a different clinical entity than in adults and is almost never due to intra-articular pathology. These lesions are usually treated conservatively and rarely require surgery.

- Ultrasound (CPT® 76881 or 76882) is the medically necessary initial imaging study.
- MRI without contrast (CPT® 73721) is medically necessary for preoperative planning or if ultrasound is non-diagnostic.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion (PEDMS-13)

v2.0.2026

Ultrasound is recommended as a first-line imaging modality for Baker's cyst detection. High accuracy has been reported with sensitivity ranging from 94% to 97% and specificity approaching 100% compared with MRI in pediatric and adult populations. Ultrasound offers practical advantages including portability, low cost, rapid acquisition, and absence of ionizing radiation, making it particularly suitable for children. Ultrasound is also well suited for follow-up of known Baker's cysts and for screening in clinical or population settings due to its accessibility and strong diagnostic performance.[1,2]

For children aged 5 years and older presenting with chronic knee pain, the American College of Radiology (ACR) recommends that when initial imaging is non-diagnostic, MRI without contrast is usually appropriate for comprehensive evaluation of intra-articular structures. MRI and ultrasound generally provide concordant information on cyst presence, but MRI adds detail on associated meniscal or cartilage pathology when clinically relevant. Additional details from MRI may be necessary for preoperative planning. Sedation may be necessary for MRI in younger children due to longer acquisition times and the need for stillness, which may involve risk of complications such as respiratory depression.[1,2]

Slipped Capital Femoral Epiphysis (SCFE) (PEDMS-14)

MSP.FE.0014.A
v2.0.2026

Slipped capital femoral epiphysis (SCFE) should be considered in young adolescents or preadolescents with groin, anterior thigh, or atraumatic knee pain. Symptoms often include a history of intermittent limp and pain for several weeks or months that are often poorly localized to the thigh, groin, or knee. Any obese adolescent or preadolescent presenting with a history of a limp and thigh, knee, or groin pain for several weeks to one month should be presumed to have a slipped capital femoral epiphysis (SCFE).

Imaging studies:

- Anteroposterior and lateral x-rays (frog leg or cross table lateral) of both hips will confirm or exclude the diagnosis.
  - If clinical suspicion remains after negative plain films, MRI without contrast (CPT® 73721) or without and with contrast (CPT® 73723) is medically necessary to detect widening of the physis before the femoral head is displaced (pre-slip).
- Because a significant percentage of SCFE is bilateral at presentation, it is medically necessary to evaluate the contralateral hip if requested, as some surgeons advocate surgical treatment of pre-slip.
- If MRI was not completed for diagnosis, MRI without contrast (CPT® 73721) is medically necessary for preoperative planning.

Club Foot (PEDMS-16.2)

MSP.CD.0016.2.A
v2.0.2026

Club Foot is a congenital foot contracture with foot in equinus (plantar flexion) and heel and forefoot in varus/adduction (turned in). Immediate diagnosis and specialty evaluation in the first week of life provide the best chance for successful correction.

- Plain x-rays should be performed initially since the anomaly is readily visible in older children and adults.
- Ultrasound (CPT® 76881 or 76882) is medically necessary to characterize the cartilaginous tarsal bones and demonstrate tarsal bone alignment in infants with non-ossified tarsal bones.
- MRI (CPT® 73718) or CT (CPT® 73700) is medically necessary to determine residual deficits following repair.
  - Ultrasound is not required prior to MRI or CT if those studies are appropriate.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Femoral Anteversion and Tibial Torsion (PEDMS-16.4)

MSP.CD.0016.4.A
v2.0.2026

- Femoral anteversion is a rotational deformity of the femur, which may lead to an in-toeing gait.
- Tibial torsion is a rotational deformity of the tibia that may lead to in-toeing or out-toeing gait, and can be associated with the foot deformities already discussed in **Tarsal Coalition (Calcaneonavicular Bar/Rigid Flat Foot) (PEDMS-16.1)**, **Club Foot (PEDMS-16.2)**, and **Vertical Talus (PEDMS-16.3)**.
- Both deformities are typically diagnosed on clinical examination, but CT Lower Extremity without contrast (CPT® 73700) OR MRI Lower Extremity without contrast (CPT® 73718) is medically necessary for preoperative evaluation.

General Guidelines (PEDCD-1.0)

CDP.GG.0001.0.A
v1.0.2026

Heart disease in the pediatric population involves predominantly congenital lesions. Pediatric individuals can have acquired heart disease unique to children. For those diseases which occur in both pediatric and adult populations, differences exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.

Pediatric Cardiac Imaging Appropriate Clinical Evaluation

- Prior to considering advanced imaging (CT, MR, Nuclear Medicine) or echocardiogram, a pertinent clinical evaluation should be performed, including the following (both):
  - A detailed history, physical examination, or meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging)
  - A review of appropriate diagnostic studies (laboratory, EKG, echocardiogram, and other diagnostic imaging)
- A recent clinical evaluation is not needed prior to advanced imaging (CT, MR, Nuclear Medicine) or echocardiogram if **any** of the following apply:
  - Individual is undergoing guideline-supported scheduled imaging evaluation.
  - Echocardiogram is being performed at the first cardiology visit for an appropriate indication as stated in these guidelines.
  - Routine imaging is anticipated at the next visit (e.g., one year follow-up echocardiogram for a 10 year old with a VSD).
- Advanced imaging of the heart and echocardiogram are medically necessary in any of the following:
  - Individuals who have documented active clinical signs or symptoms of disease involving the heart
  - As follow-up for findings on echocardiograms
  - See **Initial Transthoracic Echocardiography (TTE) Indications (PEDCD-8.2)** for indications for initial echocardiogram in asymptomatic individuals
- Repeat imaging studies of the heart are **not** medically necessary unless one of the following applies:
  - Repeat imaging is considered medically necessary in a specific guideline section.
  - There is evidence for progression of disease.
  - There is new onset of disease with documentation of how repeat imaging will affect individual management or treatment decisions.

  - See **Repeat Transthoracic Echocardiography Indications (PEDCD-8.3)** for indications for repeat echocardiogram in asymptomatic individuals
- Asymptomatic individuals with exposure to cardiotoxic drugs can have serial echocardiograms as per **Cardiotoxicity and Echocardiography (PEDONC-19.2)** in the Pediatric Oncology Imaging Guideline.
- Advanced imaging and echocardiogram is **not** medically necessary, in the absence of other appropriate indications listed in these guidelines, for **any** of the following:
  - Individuals starting ADHD medications
  - To screen asymptomatic individuals for disorders involving the heart

Pediatric Cardiac Imaging Modality General Considerations

- MRI
  - MRI and MRA studies are frequently medically necessary for evaluation of congenital heart defects not well visualized on echocardiography, thoracic arteries and veins not visualized on echocardiography, cardiomyopathies, and right ventricular disease, as well as in follow-up for these indications.
  - Due to the length of time for image acquisition and the need for the individual to be motionless during the acquisition, anesthesia is required for almost all infants and young children (age <7 years), as well as older children with delays in development or maturity. In this population, MRI imaging sessions should be planned with a goal of avoiding a short-interval repeat anesthesia exposure due to insufficient information using the following considerations:
    - MRI is typically performed without and with contrast.
    - If multiple body areas are supported for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session.
- CT
  - CT is primarily used to evaluate the coronary and great vessels in congenital heart disease if cardiac MR is contraindicated.
  - Coding considerations are listed in **CT Heart and Coronary Computed Tomography Angiography (CCTA) General Considerations (PEDCD-10.1)**
- Ultrasound
  - Echocardiography is the primary modality used to evaluate the anatomy and function of the pediatric heart and is generally indicated before considering other imaging modalities.
  - Coding considerations are listed in **Transthoracic Echocardiography (TTE) Coding (PEDCD-8.1)**
- Nuclear Medicine

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- SPECT, PET stress may be medically necessary for individuals with anomalous CA, angina chest pain, and follow-up for Kawasaki and MIS-C. See specific sections for those indications.
- Multi Gated Acquisition (MUGA) studies (CPT® 78472, CPT® 78473, CPT® 78481, CPT® 78483, CPT® 78494, or CPT® 78496) are rarely performed in pediatrics but can be approved for the following:
  - Certain pediatric oncology individuals when echocardiography is insufficient: See: **Appropriate Clinical Evaluations (PEDONC-1.2)** for imaging guidelines.
  - Quantitation of left ventricular function when recent echocardiogram shows ejection fraction of <50% and MUGA results will impact acute patient care decisions.
- SPECT/CT fusion imaging involves SPECT (MPI) imaging and CT for optimizing location, accuracy, and attenuation correction combines functional and anatomic information.
  - There is currently no evidence-based data to formulate appropriateness criteria for SPECT/CT fusion imaging.
  - Combined use of nuclear imaging, including SPECT, along with diagnostic CT (fused SPECT/CT) is considered investigational.
- Central C-V Hemodynamics (CPT® 78414) is not an imaging study and is an outdated examination.
- Cardiac Shunt Detection (CPT® 78428) is rarely performed in pediatrics but is medically necessary for individuals in whom Cardiac MR is not diagnostic.
  - Calculation of left and right ventricular ejection fractions
  - Assessment of wall motion
  - Quantitation of right to left shunts
- Myocardial Tc-99m Pyrophosphate Imaging
  - Infarct Avid Myocardial Imaging studies (CPT® 78466, CPT® 78468, and CPT® 78469), or Myocardial Tc-99m Pyrophosphate Imaging, although still available, has variable sensitivity and specificity for identifying infarcted myocardial tissue, and the current use for this indication is limited
  - CPT® 78466, CPT® 78468, and CPT® 78469, CPT® 78800 or CPT® 78803 may be used for identification of myocardial ATTR (transthyretin) amyloidosis. See **Myocardial Tc-99m Pyrophosphate Imaging in Cardiac Amyloidosis (CD-3.8)**

Pediatric Age

- Age definitions for pediatric individuals (for purpose of these guidelines)
  - Infant (birth through 12 months)
    - Neonate or newborn (birth through 28 days)
  - Child 1-18 years

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Pre-adolescent child 1-10 years
- Adolescent 11-18 years

◦ Children or Pediatric refers to all individuals ages birth-18 years

MUGA (Multi Gated Acquisition) – Blood Pool Imaging	CPT®
Myocardial Imaging, infarct avid, planar, qualitative or quantitative	78466
Myocardial Imaging, infarct avid, planar, qualitative or quantitative with ejection fraction by first pass technique	78468
Myocardial Imaging, infarct avid, planar, qualitative or quantitative tomographic SPECT with or without quantification	78469
Radiopharmaceutical Localization Imaging Limited area	78800
Radiopharmaceutical Localization Imaging SPECT Note: When reporting CPT® 78803, planar imaging of a limited area or multiple areas should be included with the SPECT	78803

Supporting Information

Individuals who are <18 years old should be imaged according to the Pediatric Cardiac Imaging Guidelines and the general Cardiac Imaging Guidelines. Individuals who are age ≥18 years should be imaged according to the Cardiac Imaging Guidelines, except where directed otherwise by a specific guideline section. Adult individuals who also have congenital heart disease should be imaged by **Congenital heart disease – General Information (CD-11.1)** in the general Cardiac Imaging Guidelines.

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount, and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Procedure Codes Associated with Cardiac or PVD Imaging

MRI/MRA	CPT®
Cardiac magnetic resonance imaging for morphology and function without contrast material	75557

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

MRI/MRA	CPT®
Cardiac magnetic resonance imaging for morphology and function without contrast material; with stress imaging	75559
Cardiac magnetic resonance imaging for morphology and function without contrast material(s), followed by contrast material(s) and further sequences	75561
Cardiac magnetic resonance imaging for morphology and function without contrast material(s), followed by contrast material(s) and further sequences; with stress imaging	75563
Cardiac magnetic resonance imaging for velocity flow mapping (List separately in addition to code for primary procedure)	75565

CT	CPT®
Computed tomography, heart, without contrast material, with quantitative evaluation of coronary calcium	75571
Computed tomography, heart, with contrast material, for evaluation of cardiac structure and morphology (including 3D image postprocessing, assessment of cardiac function, and evaluation of venous structures, if performed)	75572
Computed tomography, heart, with contrast material, for evaluation of cardiac structure and morphology in the setting of congenital heart disease (including 3D image postprocessing, assessment of LV cardiac function, RV structure and function and evaluation of venous structures, if performed)	75573

CTA	CPT®
Noninvasive estimate of coronary fractional flow reserve (FFR) derived from augmentative software analysis of the data set from a coronary computed tomography angiography, with interpretation and report by a physician or other qualified health care professional	75580

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CTA	CPT®
Computed tomographic angiography, heart, coronary arteries and bypass grafts (when present), with contrast material, including 3D image postprocessing (including evaluation of cardiac structure and morphology, assessment of cardiac function, and evaluation of venous structures, if performed)	75574
Computed tomographic angiography, abdominal aorta and bilateral iliofemoral lower extremity runoff, with contrast material(s), including noncontrast images, if performed, and image postprocessing	75635

Nuclear Medicine	CPT®
Determination of central c-v hemodynamics (non-imaging) (e.g., ejection fraction with probe technique) with or without pharmacologic intervention or exercise, single or multiple determinations	78414
Cardiac shunt detection	78428
Myocardial imaging, positron emission tomography (PET), metabolic evaluation study (including ventricular wall motion[s] and/or ejection fraction[s], when performed), single study; with concurrently acquired computed tomography transmission scan	78429
Myocardial imaging, positron emission tomography (PET), perfusion study (including ventricular wall motion[s] and/or ejection fraction[s], when performed); single study, at rest or stress (exercise or pharmacologic), with concurrently acquired computed tomography transmission scan	78430
Myocardial imaging, positron emission tomography (PET), perfusion study (including ventricular wall motion[s] and/or ejection fraction[s], when performed); multiple studies at rest and stress (exercise or pharmacologic), with concurrently acquired computed tomography transmission scan	78431

Nuclear Medicine	CPT®
Myocardial imaging, positron emission tomography (PET), combined perfusion with metabolic evaluation study (including ventricular wall motion[s] and/or ejection fraction[s], when performed), dual radiotracer (e.g., myocardial viability);	78432
Myocardial imaging, positron emission tomography (PET), combined perfusion with metabolic evaluation study (including ventricular wall motion[s] and/or ejection fraction[s], when performed), dual radiotracer (e.g., myocardial viability); with concurrently acquired computed tomography transmission scan	78433
Absolute quantitation of myocardial blood flow (AQMBF), positron emission tomography (PET), rest and pharmacologic stress (List separately in addition to code for primary procedure)	78434
Myocardial perfusion imaging, tomographic (SPECT) (including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic)	78451
Myocardial perfusion imaging, tomographic (SPECT) (including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection	78452
Myocardial perfusion imaging, planar (including qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic)	78453
Myocardial perfusion imaging, planar (including qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection	78454

Nuclear Medicine	CPT®
Myocardial imaging, positron emission tomography (PET), metabolic evaluation study (including ventricular wall motion and/or ejection fraction, when performed), single study	78459
Myocardial imaging, infarct avid, planar; qualitative or quantitative	78466
Myocardial imaging, infarct avid, planar; with ejection fraction by first pass technique	78468
Myocardial imaging, infarct avid, planar; tomographic SPECT with or without quantification	78469
Cardiac blood pool imaging, gated equilibrium; planar, single study at rest or stress (exercise and/or pharmacologic), wall motion study plus ejection fraction, with or without additional quantitative processing	78472
Cardiac blood pool imaging, gated equilibrium; multiple studies, wall motion study plus ejection fraction, at rest and stress (exercise and/or pharmacologic), with or without additional quantification	78473
Cardiac blood pool imaging (planar), first pass technique; single study, at rest or with stress (exercise and/or pharmacologic), wall motion study plus ejection fraction, with or without quantification	78481
Cardiac blood pool imaging (planar), first pass technique; multiple studies, at rest and with stress (exercise and/or pharmacologic), wall motion study plus ejection fraction, with or without quantification	78483
Myocardial imaging, positron emission tomography (PET), perfusion (including ventricular wall motion and/or ejection fraction, when performed); single study at rest or stress (exercise or pharmacologic)	78491
Myocardial imaging, positron emission tomography (PET), perfusion (including ventricular wall motion and/or ejection fraction, when performed); multiple studies at rest and/or stress (exercise or pharmacologic)	78492

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Nuclear Medicine	CPT®
Cardiac blood pool imaging, gated equilibrium, SPECT, at rest, wall motion study plus ejection fraction, with or without quantitative processing	78494
Cardiac blood pool imaging, gated equilibrium, single study, at rest, with right ventricular ejection fraction by first pass technique (List separately in addition to code for primary procedure)	78496
Quantitative differential pulmonary perfusion, including imaging when performed	78597
Quantitative differential pulmonary perfusion and ventilation (e.g., aerosol or gas), including imaging when performed	78598
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, single area (e.g., head, neck, chest, pelvis), single day imaging	78800
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, 2 or more areas (e.g., abdomen and pelvis, head and chest), 1 or more days imaging or single area imaging over 2 or more days	78801
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, whole body, single day imaging	78802
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT), single area (e.g., head, neck, chest, pelvis), single day imaging	78803
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, whole body, requiring 2 or more days imaging	78804

Proprietary Information of UnitedHealthcare.

Nuclear Medicine	CPT®
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT) with concurrently acquired computed tomography (CT) transmission scan for anatomical review, localization and determination/detection of pathology, single area (e.g., head, neck, chest, pelvis), single day imaging	78830
Myocardial sympathetic innervation imaging, planar qualitative and quantitative assessment	0331T
Myocardial sympathetic innervation imaging, planar qualitative and quantitative assessment; with tomographic SPECT	0332T

Ultrasound	CPT®
Transthoracic echocardiography for congenital cardiac anomalies; complete	93303
Transthoracic echocardiography for congenital cardiac anomalies; follow-up or limited study	93304
Echocardiography, transthoracic, real-time with image documentation (2D), includes M-mode recording, when performed, complete, with spectral Doppler echocardiography, and with color flow Doppler echocardiography	93306
Echocardiography, transthoracic, real-time with image documentation (2D), includes M-mode recording, when performed, complete, without spectral or color Doppler echocardiography	93307
Echocardiography, transthoracic, real-time with image documentation (2D), includes M-mode recording, when performed, follow-up or limited study	93308
Echocardiography, transesophageal, real-time with image documentation (2D) (with or without M-mode recording); including probe placement, image acquisition, interpretation and report	93312

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Congenital Heart Disease General Information (PEDCD-2.1)

CDP.CHD.0002.1.A
v1.0.2026

- Congenital heart disease accounts for the majority of cardiac problems occurring in the pediatric population. Individuals may be diagnosed any time spanning prenatal evaluation to adolescence. For diagnostic and surveillance imaging of individuals over 18 years of age, see **Congenital heart disease – General Information (CD-11.1)** in the general Cardiac Imaging Guidelines.
- There are a number of variables that influence the modality and timing of imaging individuals with congenital heart disease, which results in a high degree of individuality in determining the schedule for imaging these individuals, including:
  - Gestational age
  - Individual's age
  - Physiologic effects of the defect
  - Status of interventions (catheterization and surgical)
  - Rate of individual's growth
  - Stability of the defect on serial imaging
  - Comorbid conditions
  - Activity level
- Age definitions for pediatric individuals (for purpose of these guidelines)
  - Infant (birth through 12 months)
    - Neonate or newborn (birth through 28 days)
  - Child 1-18 years
    - Pre-adolescent child 1-10 years
    - Adolescent 11-18 years
  - Children or Pediatric refers to all individuals ages birth-18 years
- Newborns (neonates) have special considerations as they have potentially rapidly changing physiology.
  - Newborns with any concerns for ductal dependent lesion can have echocardiograms at any frequency.
  - Newborns have changes in pulmonary vascular resistance that can affect clinical status rapidly and may require more frequent imaging.
  - Neonatal physiology can extend to the first couple of months of life.
  - Newborns can have one repeat echo, if prior echocardiogram is abnormal or equivocal (either in the hospital or as newborn outpatient).

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Individuals can have an echocardiogram at that time for **Change in clinical status and/or new concerning signs or symptoms**. This can include:
  - Shortness of breath
  - Fatigue
  - Chest discomfort
  - Percentile weight loss
  - Weight gain
  - Poor feeding
  - Tachypnea
  - Tachycardia
  - CHF signs on exam
  - Change in EKG, Pulse ox, or laboratory values
- An additional study can be approved prior to the next routine interval to assess for more rapid change if the change in clinical status involves the echocardiogram itself, such as:
  - Increasing stenosis gradient
  - Increasing regurgitation amount
  - Increasing pulmonary vascular resistance
  - Decreased ventricular function
  - Change in ductal status
- In individuals that can have both Cardiac MR or Cardiac CT and/or MRA Chest or CTA Chest, this is abbreviated as CMR/CT-MRA/CCTA.
- Individuals with medication adjustments may require additional imaging at that time.
  - Pediatric dosing tends to be mg/kg or mcg/kg. Adjusting the dose to the same mg/kg would not be considering a dosing change for imaging.
  - More than one echocardiogram is considered medically necessary in infants due to rapid growth in this age group, changing physiology, pulmonary vascular resistance, ductal size and weight changes, because dose adjustments are done by weight, and dose response and may require more than one echocardiogram during a medication adjustment.
- Heart surgery
  - TTE is considered medically necessary one month prior to heart surgery. Depending on lesion, MR/CT Cardiac and/or Chest may also be included.
  - Can have an echocardiogram within one month post-operative
  - Cardiac MRI/CCT if prior echocardiogram is equivocal
- MRA/CTA Chest can be performed if prior echocardiogram is equivocal and there are issues regarding aortic arch or pulmonary arteries or veins.
- In individuals who have a documented equivocal echocardiogram due to a technical factor (i.e., poor acoustic windows due to body habitus) which will likely be present

Click Here to Return to the Main TOC

on subsequent echocardiograms, a Cardiac MR/CT, or MRA/CTA Chest may be done with the frequency of echoes, if done instead of an echo.

- MRA/CTA Chest if thoracic issue not seen on echo
- For routine non-invasive imaging for a specific lesion see **Imaging and Surveillance per Congenital Lesion (PEDCD-2.4)**
- For catheterizations see section **Cardiac Catheterization - Indications (PEDCD-11.2)**
- **Individuals with Pulmonary hypertension with CHD** should be reviewed for both their lesion and for PHT in section **Pediatric Pulmonary Hypertension General (PEDCD-7.1)**

Congenital Heart Disease Coding (PEDCD-2.2)

CDP.CHD.0002.2.A
v1.0.2026

Congenital Heart Disease Echocardiography Coding (PEDCD-2.2.1)

- **Any** of the following echocardiography code combinations are appropriate for re-evaluation of individuals with known congenital heart disease:
  - CPT® 93303, CPT® 93320, and CPT® 93325
  - CPT® 93304, CPT® 93321, and CPT® 93325
  - CPT® 93303
  - CPT® 93304
- CPT® 93306 is not medically necessary in the evaluation of known congenital heart disease.

Congenital Heart Disease imaging per modality (PEDCD-2.2.2)

Echocardiogram

- Transthoracic echocardiogram (TTE)
  - TTE for congenital cardiac anomalies; complete (CPT® 93303)
  - TTE for congenital cardiac anomalies; limited study (CPT® 93304)
  - TTE (2D) m-mode recording, complete, with spectral and color flow doppler echocardiography (CPT® 93306)
  - TTE (2D) with or without m-mode recording; complete (CPT® 93307)
  - TTE (2D) with or without m-mode recording; limited study (CPT® 93308)
- Transesophageal echocardiogram (TEE)
  - TEE (2D) including probe placement, imaging, interpretation, and report (CPT® 93312)
  - TEE for congenital cardiac anomalies; including probe placement, imaging, interpretation, and report (CPT® 93315)

MRI

- Cardiac (CMR)
  - Cardiac MRI for morphology and function without contrast (CPT® 75557)
  - Cardiac MRI for morphology and function without and with contrast (CPT® 75561)
  - Cardiac magnetic resonance imaging for velocity flow mapping (List separately in addition to code for primary procedure) (CPT® 75565)
- MRI Chest

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI Chest without contrast (CPT® 71550)
- MRI Chest with contrast (CPT® 71551)
- MRI Chest with & without contrast (CPT® 71552)

- MRI Angiography (MRA)
  - MRA Chest (excluding myocardium) with or without contrast (CPT® 71555)

CT

- Cardiac (CCT)
  - CT, Heart, with contrast material, for evaluation of cardiac structure and morphology (CPT® 75572)
  - CT, Heart, with contrast material, for evaluation of cardiac structure and morphology in the setting of congenital heart disease (CPT® 75573)
- CT Angiography-Cardiac (CCTA)
  - CTA Heart, coronary arteries and bypass grafts (when present), with contrast, including 3D image post processing (CPT® 75574)
- CT-Chest
  - CT Thorax without contrast (CPT® 71250)
  - CT Thorax with contrast (CPT® 71260)
  - CT Thorax without & with contrast (CPT® 71270)
- CT Angiography-Chest (CTA Chest)
  - CTA Chest without and with contrast (CPT® 71275)

Stress Imaging (echo, MRI, MPI)

- Stress echo
  - Echocardiography (TTE), (2D), with or without m-mode, during rest and cardiovascular stress, with interpretation and report (CPT® 93350)
  - Echocardiography (TTE), (2D), m-mode, during rest and cardiovascular stress test using treadmill, bicycle exercise and/or pharmacologically induced stress, with interpretation (CPT® 93351)
- Stress MRI
  - Cardiac MRI for morphology and function without contrast, with stress imaging (CPT® 75559)
  - Cardiac MRI for morphology and function without and with contrast, with stress imaging (CPT® 75563)
- Myocardial perfusion imaging (MPI)
  - MPI, tomographic (SPECT) including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic) (CPT® 78451)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MPI, tomographic (SPECT) (including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection (CPT® 78452)

Pulmonary perfusion imaging

- Pulmonary perfusion imaging (e.g., particulate) (CPT® 78580)
- Pulmonary ventilation (e.g., aerosol or gas) and perfusion imaging (CPT® 78582)
- Quantitative differential pulmonary perfusion, including imaging when performed (CPT® 78597)
- Quantitative differential pulmonary perfusion and ventilation (e.g., aerosol or gas), including imaging when performed (CPT® 78598)

Proprietary Information of UnitedHealthcare.

Congenital Heart Disease Modality Considerations (PEDCD-2.3)

CDP.CHD.0002.3.A
v1.0.2026

- Echocardiography is the primary imaging modality used for diagnosing and monitoring congenital heart disease and is generally required before other imaging modalities are considered medically necessary unless otherwise indicated in a specific guideline section.
- Cardiac MRI either without contrast (CPT® 75557) or without and with contrast (CPT® 75561) is considered medically necessary when a recent echocardiogram is inconclusive, needs confirmation of findings, or does not completely define the disease (for subsequent follow-up studies, a recent echocardiogram is not a requirement).
  - CPT® 75565 is also medically necessary for individuals with valvular disease or a need to evaluate intracardiac blood flow. These individuals will usually have CPT® 93320 and CPT® 93325 performed with their echocardiography studies.
  - MRA Chest (CPT® 71555) may be added if the aorta or pulmonary artery needs to be visualized beyond the root or if aortopulmonary collaterals, pulmonary veins, or systemic veins need to be visualized.
    - MRA Chest alone (CPT® 71555) should be performed if the individual cannot cooperate with full cardiac MRI exam.
- MRA Chest (CPT® 71555) is considered medically necessary for assessment of the great arteries, pulmonary veins, and systemic chest veins with inconclusive recent echocardiography findings, including the following:
  - Coarctation of the aorta
  - Tetralogy of Fallot
  - Anomalous pulmonary veins
  - Transposition of the great arteries
  - Truncus arteriosus
  - Vascular rings and other lesions of the great arteries, with inconclusive recent echocardiography findings
- CT imaging is considered medically necessary when recent echocardiogram is inconclusive:
  - Report CPT® 75574 for evaluating coronary artery anomalies
  - Report CPT® 75573 for congenital heart disease
  - CPT® 71275 Determination of vascular extra-cardiac anatomy in individuals with complex congenital heart disease

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - Pulmonary artery (PA) and Pulmonary vein (PV) assessment
- CTA Chest (CPT® 71275) is considered medically necessary with inconclusive recent echocardiography findings to assess:
  - Coarctation of the aorta
  - Tetralogy of Fallot
  - Anomalous pulmonary veins and other lesions of the great arteries
  - Vascular rings
- Pulmonary perfusion imaging
  - Pulmonary perfusion imaging (e.g., particulate) (CPT® 78580)(CPT® 78582) (CPT® 78597)(CPT® 78598)
  - Individuals with congenital heart disease or suspected congenital heart diseases, who have clinical questions regarding relative pulmonary blood flow, can have perfusion imaging.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Imaging and Surveillance per Congenital Lesion (PEDCD-2.4)

CDP.CHD.0002.4.A
v1.0.2026

- Echocardiography is often repeated frequently throughout a pediatric individuals life and can generally be approved regardless of symptoms based on the lesion and age of the individual. These are listed in sections in sections below.
  - Modifiers following guidelines
    - Some congenital conditions may require more frequent testing, especially with more complex heart disease, congestive heart failure, obstructive heart lesions, ductal dependent lesions, changes in clinical status, repeat interventions, and/or in neonates.
    - Any individual being treated for heart failure, with consideration for changing medical regimen can have an echocardiogram.
- Echocardiography is performed during the physician office visit, and these studies should not be denied because of lack of recent contact.
- Adults 18 years and older who also have congenital heart disease should be imaged according to **Congenital heart disease – General Information (CD-11.1)**

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Atrial Defects-Secundum ASD, PFO, and Partial Anomalous Pulmonary Venous Return (PAPVR), Sinus Venosus Defect (PEDCD-2.4.1)

CDP.CHD.0241.A
v1.0.2026

For imaging in AVSD see **AVSD (Atrioventricular canal, endocardial cushion defect) (PEDCD-2.4.3)**

PFO (Patent Foramen Ovale)

- Routine surveillance in an asymptomatic individual with PFO is not medically necessary.
  - PFO is a normal variant.
  - In infants, a PFO that is difficult to distinguish from an ASD can be imaged with the same guidelines as used in a small unrepaired ASD (with congenital echo).
  - Individuals with PFOs may have an additional indication for an echocardiogram and can be imaged according to the echocardiogram guidelines in **Repeat Transthoracic Echocardiography Indications (PEDCD-8.3)** and **Congenital Heart Disease Modality Considerations (PEDCD-2.3)** in the general Cardiac Imaging Guidelines.
- Follow-up imaging with an echocardiogram is considered medically necessary when there is documentation of the following:
  - New cardiac symptoms
  - A concern that the last echocardiogram was equivocal for other cardiac issues
  - Question of a clot/embolism that has gone across the PFO
  - Prior echocardiogram did not differentiate the PFO from a secundum ASD
- TTE (CPT® 93306- non congenital echocardiogram) is considered medically necessary when an individual with a prior history of PFO requires an echocardiogram for any new reason.
- Preoperative for PFO closure
  - TTE or TEE
    - Closure is rare in children, TTE or TEE is medically necessary in individuals with transient ischemic attacks or strokes with suspected atrial level shunt.
    - CMR/CT-CMRA/CTA if unclear findings from echocardiogram
- Intra-procedural PFO

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Intra-procedural TEE (CPT® 93355) is not in scope for this program.
- Post procedure PFO closure
  - Post-surgical imaging as follows (PFO generally requires less frequent monitoring post device than ASDs):
    - TTE one time within 30 days of closure
    - TTE one time within 6 months of PFO closure
  - TTE or TEE is considered medically necessary at any time post procedure when there is concern for **any** of the following:
    - Infection
    - Malposition
    - Embolization
    - Persistent shunt
      - For persistent shunt, TTE is considered medically necessary every 3 months until the finding is stable or there is a need for intervention
  -

Secundum ASD, Sinus Venosus ASD, Asymptomatic Isolated (ASD) and Unobstructed (PAPVR)

- Any surgical status
  - TTE is considered medically necessary for any of the following:
    - Initial evaluation of a change in clinical status and/or new concerning signs or symptoms
    - Prior to planned cardiac intervention
    - Repeat any time prior to next allowed study if concern for elevated pulmonary vascular resistance/Pulmonary hypertension
  - CMR/CT-CMRA/CTA
    - If anomalous vein or SV defect cannot be assessed on echo
    - To assess shunt or RV for considering of surgery, or if echocardiogram equivocal
- Unrepaired
  - Newborn with isolated ASD can have one repeat TTE within 2 months
  - Small asymptomatic isolated ASD with no pulmonary hypertension can have TTE as follows:
    - Infant <6 months every three months
    - Infant ≥6 months, repeat at one year.
    - Child Every 3 years
  - Routine surveillance for ≥moderate ASD or PAPVR >1 vein
    - Infant every 3 months
    - Echocardiogram (TTE) every 1 year

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Prior to planned repair of ASD
  - TTE and/or TEE
  - MRI if any residual issues unanswered by echo
- Prior to planned SV defect or PAPVR
  - TTE and/or TEE
  - CMR/CT-CMRA/CTA
- Post- ASD closure with device
  - TTE post device closure
    - 1 week
    - 1 month
    - Every 3 months
    - 1 year
    - Every 2 years
  - May repeat TTE every 3 months until the finding is stable or there is a need for intervention if there is significant residual shunt, valvular or ventricular dysfunction, arrhythmias, and/or pulmonary hypertension
- Post-surgical closure of ASD
  - TTE
    - Within the first month
    - Within the 1st year
    - Every 2 years after the first year study
  - May repeat TTE every 3 months until the finding is stable or there is a need for intervention if significant residual shunt, valvular or ventricular dysfunction, arrhythmias, and/or pulmonary hypertension

Proprietary Information of UnitedHealthcare.

Ventricular Septal Defect (VSD) (PEDCD-2.4.2)

CDP.CHD.0242.A
v1.0.2026

All

TTE is considered medically necessary for any of the following:

- Change in clinical status and/or new concerning signs or symptoms
- Prior to planned cardiac intervention

Unrepaired

TTE

- Small muscular VSD, No Symptoms, No pulmonary hypertension
  - Newborn 1 repeat within 2 months
  - Infant every 6 months
  - Child every 3 years
- Small VSD in location other than muscular
  - Newborn 1 repeat TTE within 2 months
  - Infant TTE every 6 months
  - Child TTE every year
- Moderate or large VSD on medical management
  - Newborn TTE every 2 weeks
  - Infant every 1-month
  - Child <2 years old TTE every 3 months
  - Child >2 years old TTE every year

Post Repair VSD

TTE

- One study within one month of surgery
- One study within one year of surgery
- After first year of surgery, every 2 years
- Following surgical or device closure in an individual with significant residual shunt, valvular or ventricular dysfunction, arrhythmias, and/or pulmonary hypertension
  - Pre-adolescent Child (age 1-10)-TTE every 3 months
  - Adolescent (age 11-18)- TTE every 6 months

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

AVSD (Atrioventricular Canal, Endocardial Cushion Defect) (PEDCD-2.4.3)

CDP.CHD.0243.A
v1.0.2026

Any surgical status

TTE is medically necessary for any of the following:

- Change in clinical status and/or new concerning signs or symptoms
- Prior to planned cardiac intervention

Unrepaired

- Partial/transitional Atrioventricular canal (AVC)
  - TTE is considered medically necessary as follows:
    - Newborn repeat once within the next 2 months
    - Infant every 3 months
    - Child <2 years every 6 months
    - Child ≥2 years, 1 year
- Complete AVC
  - TTE
    - Newborn, TTE repeat within first month
    - Infant <6 weeks, TTE every 2 weeks.
    - Infant ≥6 weeks, TTE monthly

Repaired (TTE)

- Within one month of surgery
- Within 1 year
- Then annually
- May repeat TTE every 3 months until the finding is stable or there is a need for intervention if residual shunt, valvular LV dysfunction, LVOT obstruction, arrhythmia, arrhythmia or PHT, symptoms of heart failure

Proprietary Information of UnitedHealthcare.

PDA (Patent Ductus Arteriosus) (PEDCD-2.4.4)

CDP.CHD.0244.A
v1.0.2026

Any surgical status

TTE is considered medically necessary for any of the following:

- Initial evaluation of a change in clinical status or new concerning signs or symptoms
- Prior to planned cardiac intervention

Unrepaired

- Newborn, one repeat TTE in newborn period
  - None, if spontaneously closed
- >1-year-old
  - No Routine surveillance in an asymptomatic individual with a trivial, silent PDA
- Infant
  - Small PDA: TTE every 3 months
  - ≥ Moderate PDA: TTE every month
- Pre-adolescent Child
  - Small PDA: every 1 year
  - Moderate PDA: every 6 months
- Adolescent every 3 years

Post PDA device

- Post procedure surveillance (TTE)
  - One echo in first 30 days
  - Annually for first 2 years
  - Every 5 years after first 2 years
- Post procedure LPA stenosis or aortic obstruction
  - Pre-adolescent Child
    - TTE annually
    - MRA/CTA Chest, or (lung perfusion for LPA stenosis) if questions remain unanswered after TTE
  - Adolescents
    - Every two years TTE and

TAPVR Total Anomalous Pulmonary Venous Return (PEDCD-2.4.5)

CDP.CHD.0245.A
v1.0.2026

Any surgical status
- TTE, TEE, CMR/CT-CMRA/CTA, Lung perfusion scan are considered medically necessary for any of the following:
  - Change in clinical status and/or new concerning signs or symptoms
  - Prior to planned cardiac intervention

Unrepaired
- No restrictions

Repaired
- TTE one Post procedure evaluation first 30 days
- TTE every 3 months in infancy
- Pre-adolescent Child: every 1 year
- Adolescence: TTE every 2 years

Proprietary Information of UnitedHealthcare.

Ebstein Anomaly and TV Dysplasia (PEDCD-2.4.6)

CDP.CHD.0246.A
v1.0.2026

Any surgical status
- TTE, TEE, CMR/CT-CMRA/CTA are considered medically necessary for any of the following:
  - Change in clinical status and/or new concerning signs or symptoms
  - Prior to planned repair or intervention

Unrepaired
- Newborn repeat study within 30 days.
- Infant
  - Trivial TR is a normal finding
  - Mild TR- TTE every year
  - ≥ Moderate TR- TTE every 3 months
- Child
  - Mild TR every year TTE
  - ≥ Moderate every 6 months

Repaired (TTE)
- Post-op within 30 days
- TTE once a year
- TTE every 6 months if valvular or ventricular dysfunction, or arrhythmias
- Pre-adolescent Child: every year
- Adolescent: every 2 years
- Every 3 months if CHF or atrial arrhythmias

Proprietary Information of UnitedHealthcare.

Pulmonary Stenosis (PS) (PEDCD-2.4.7)

CDP.CHD.0247.A
v1.0.2026

Any surgical status
- TTE is considered medically necessary for any of the following:
  - Change in clinical status and/or new concerning signs or symptoms
  - Prior to planned cardiac procedure
  - If increasing gradient, 1 additional study prior to next allowed study
  - PS in Williams syndrome: See **LVOT Lesions (PEDCD-2.4.10)**

Unrepaired
- Neonate
  - TTE repeat study within 30 days
- Infant PS asymptotic (any severity)
  - TTE every 3 months
- Pre-adolescent Child
  - TTE every 1 year
- Adolescent
  - TTE every 2 years
  - MRA/CTA Chest if pulmonary artery dilation every 3 years

Post procedure (TTE)
- Within 30 days
- Infant
  - TTE every 3 months
- Pre-adolescent Child
  - TTE 1 year
  - Moderate or severe sequelae TTE every 6 months
- Adolescent
  - TTE every 2 years
- Any individual with heart failure, TTE every 3 months

Pulmonary Atresia with Intact Septum (PAIVS) (PEDCD-2.4.8)

CDP.CHD.0248.A
v1.0.2026

Any surgical status

TTE is considered medically necessary for any of the following:

- Prior to planed repair
- Change in clinical status and/or new concerning signs or symptoms

Post procedural: Palliation

- TTE
  - 1 within 30 days
  - Every 1 month until repaired

Post procedural: Complete Repair

- TTE within 30 days post-op
- Any age
  - TTE every three months for CHF
- Infant
  - TTE at 3 months in asymptomatic infant
- Child (all ages)
  - TTE annually
  - Every 6 months if moderate sequelae
- Adolescent (in addition to TTE)
  - CMR/CT and/or CMRA/CTA every 3 years

Mitral Valve Disease (PEDCD-2.4.9)

CDP.CHD.0249.A
v1.0.2026

Any surgical status
- TTE is considered medically necessary for any of the following:
  - Prior to planned surgery
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms

Unrepaired congenital mitral valve stenosis
- Infant in first three months of life
  - Weekly TTE
- After 3 months (TTE)
  - Every 3 months if mild MS
  - Every month if ≥ moderate MS
- Child (TTE)
  - With moderate MS every 3 months until a decision is made to intervene
  - Child with mild symptoms annually

Unrepaired: Congenital Mitral Regurgitation (MR) including Mitral Valve Prolapse
- Infant
  - TTE every 6 months an asymptomatic infant with mild MR
  - TTE every month in asymptomatic infant with ≥ moderate MR
- Child
  - TTE every 2 years with mild MR, normal LV size and systolic function
  - TTE every 6 months with ≥ moderate MR
  - TTE every 3 years in an asymptomatic with MVP and mild MR

Post procedure, surgical or catheter based
- TTE within 30 days
- Infant
  - TTE every 3 months, mild MS or MR, and no LV dysfunction
  - TTE every month in ≥ moderate MS or MR, dilated LV, and no LV dysfunction
- Child
  - TTE annually
    - In a child with normal prosthetic mitral valve function and no LV dysfunction
    - In a child with mild MS or MR, and no LV dysfunction

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

LVOT Lesions (PEDCD-2.4.10)

CDP.CHD.2410.A
v1.0.2026

Subvalvular Aortic stenosis

Any surgical status
- TTE, TEE, Cardiac MR/CT are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Preoperative
- If aortic dimension z-score >2
  - TTE or Chest CTA/MRA every 2 years if stable z-score
  - TTE or Chest CTA/MRA every 6 months if increasing z-score

Unrepaired
- Newborn- No restrictions
- Infant TTE
  - 1 monthly for any subvalvular AS, but ≤ mild AR
- Child
  - TTE one per year if mild AS and no AR
  - TTE every 6 months ≥ moderate subvalvular AS and/or mild AR
  - Routine surveillance (6–12 months) in an asymptomatic child with ≥ moderate AS and/or ≥ moderate AR

Repaired
- Infant
  - TTE within 30 days
  - TTE every 3 months ≤ mild MS and or AR
  - TTE every 1 month ≥ moderate AS or AR
- Child
  - TTE every 1 year ≤ Mild AS or AR
  - TTE every 6 months ≥ moderate AS or AR
  - TTE every 3 months if heart failure

Aortic Valve Stenosis and/or regurgitation/ BAV (Bicuspid Aortic Valve)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Any surgical status

- TTE, TEE, Cardiac MR/CT are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Preoperative

Unrepaired

- Infant <3 months
  - TTE 1 per week
- Infant >3 months
  - TTE every 3 months
  - TTE every 1 month, if ≥ moderate AS or AR
- Child
  - TTE every 1 year with mild AS/AR and no aortic dilation
  - TTE every 6 months with moderate AS/AR, or aortic dilation.
  - TTE every 3 years if BAV with trivial or mild valvular dysfunction and no aortic root dilation
  - Every 6 months in any as with increasing z-score aortic root ascending aorta

Post procedural

- Within 30 days TTE
- Infant
  - Every 1 month following neonatal intervention with ≥ moderate AS or AR or LV dysfunction
  - Every 3 months ≤ mild AS/AR and no LV dysfunction
- Child (TTE)
  - 6 months echocardiogram if ≥ moderate AS or AR
  - 1-year echocardiogram if ≤ mild AS or AR, and/or normal prosthetic valve
  - Every 3 months if CHF or Ventricular dysfunction

Supravalvular AS

Any surgical status

- TTE, TEE, Cardiac MR/CT, Chest MRA/CTA are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Preoperative
  - Williams syndrome

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - Individuals with Williams syndrome can be screened/evaluated for arch abnormalities and pulmonary artery abnormalities and coronary artery abnormalities with the same intervals as TTE referenced below.
    - Stress imaging can be done at initial evaluation and for cardiac symptoms, change in clinical status, and/or new concerning signs or symptoms

Unrepaired

- Infant
    - TTE every 3 months
- Child
    - TTE every 1 year
    - TTE every 6 months if moderate AS

Post-operative (TTE)

- Within 30 days
- Every 2 years in mild to moderate AS
- Every 6 months if ≥ moderate AS

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Aortic Coarctation and IAA (Interrupted Aortic Arch) (PEDCD-2.4.11)

CDP.CHD.2411.A
v1.0.2026

All individuals

- TTE, MRA/CTA Chest are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Prior to planned surgery/intervention
- Cardiac MR/CT is considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Prior to planned surgery/intervention if any issues remain not answered on echo

Screening for related intracranial aneurysms see **Cerebral Intracranial Aneurysms (HD-12.1)**

Unrepaired Aortic Coarctation

- Newborn, TTE weekly if assessing for ductal closure
- Infant with mild coarctation in absence of PDA
  - Echocardiogram every 3 months
- Child with mild coarctation
  - Echocardiogram every 1 year
  - MRA Chest, CTA Chest every 3 years

Post procedure: surgical or catheter based

- TTE
  - Within 30 days of procedure
  - Every 3 months if mild or no sequelae in first year
  - Every 6 months if mild or no sequelae in the second year
  - Every 1 year after the second year
  - Every 3 months at any time if CHF symptoms or ≥ moderate sequelae
- MRA/CTA Chest every 3 years (include Cardiac MR/CT if issues not clarified on echo)
- Screening for intracranial aneurysms see **Cerebral Intracranial Aneurysms (HD-12.1)**

Coronary Anomalies (PEDCD-2.4.12)

CDP.CHD.2412.A
v1.0.2026

- CCTA or cardiac MRI is considered medically necessary for evaluating coronary artery anomalies and other complex congenital heart disease of cardiac chambers or great vessels.
  - CPT® 75574 for evaluating coronary artery anomalies
  - CPT® 75573 for congenital heart disease
  - CTA Chest (CPT® 71275) can be added to evaluate great vessels.
- Congenital anomalies of the coronary arteries are an important cause of sudden death in pediatric individuals. Coronary arteries may arise from the wrong coronary artery cusp leading to ischemic changes during exercise. These lesions may be found incidentally during a murmur evaluation. Anomalous coronary arteries may be seen on echocardiogram during an evaluation for chest pain or syncope or palpitations. In addition, individuals with no echocardiographic findings but symptoms concerning for angina chest pain may require stress testing.
  - Individuals who have positive echocardiographic findings, regardless of symptoms, and individuals who have classical typical angina chest pain regardless of echocardiographic findings, may require treadmill stress testing, stress imaging, or advanced imaging such as Cardiac MRI, Stress echocardiogram, PET, Cardiac CT, and/or cardiac catheterization.
- Congenital coronary anomalies include abnormal origin of a coronary artery from the PA, anomalous aortic origin of a coronary artery from a different aortic sinus of Valsalva (left coronary artery from the right sinus of Valsalva or right coronary artery from the left sinus of Valsalva), coronary arteriovenous fistula, and coronary artery ostial atresia, all in the setting of normal conotruncal anatomy.
  - Any surgical status
    - Prior to planned surgery, or change in clinical status and/or new concerning signs or symptoms
      - TTE
      - CMR or CCT
        - Can initially include MRA/CTA Chest
        - If the origin of the coronaries arteries is below the sinus of Valsalva then a chest study is not needed on subsequent imaging.
        - If the origin of the coronary artery is not at the level of the sinus of Valsalva, a MRA/CTA Chest can be included when MR/CT imaging is required
      - Stress imaging- to assess the need for surgery

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Unrepaired
  - Routine surveillance every 2 years in an asymptomatic individual with anomalous right coronary artery from the left aortic sinus
    - TTE
    - Stress imaging
  - Although typically repaired, in the event that a repair is not completed, anomalous left coronary artery from the right coronary sinus can have imaging.
    - TTE annually
    - Stress imaging annually
  - Routine surveillance in an asymptomatic individual with small coronary fistula
    - TTE- every 2 years
  - Routine surveillance in an asymptomatic individual with moderate or large coronary fistula
    - TTE annually
- Post-procedural: surgical or catheter
  - TTE
    - Within 30 days of procedure
    - Monthly the first year following repair
    - Every 3 months after first year of surgery
    - Annually after the second year of surgery
    - Every 3 months if ventricular dysfunction
  - Stress testing
    - EKG stress testing without imaging may be medically necessary in the first post year and every 1-2 years depending on level of activity.
    - Stress testing with imaging
      - First postoperative year
      - If EKG stress test positive of equivocal
- Change in clinical status and/or new concerning signs or symptoms
- Individuals with congenital heart disease such as TOF, Truncus Arteriosus, and TGA have increased incidence of coronary artery anomalies
- Individuals with Williams syndrome can have coronary artery stenosis
- Individuals with confirmed coronary artery anomalies may require repeat imaging based on the clinical scenario
- CCTA to rule out anomalous coronary artery should be limited to one of the following:
  - Individuals who need to have an anomalous coronary artery mapped prior to an invasive procedure
  - Individuals who have not had a previous imaging study that clearly demonstrates an anomalous coronary artery

Tetralogy of Fallot (TOF) (PEDCD-2.4.13)

CDP.CHD.2413.A
v1.0.2026

Any surgical status
- TTE, CMR/CT-CMRA/CTA
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Evaluation prior to planed pulmonary valve replacement, cardiac intervention, or surgery

Unrepaired
- Newborn-TTE no limits
- Infant
  - 1 per month

Post procedure palliation
- 1 per month following palliative procedure prior to complete repair, valvuloplasty, PDA and/or RVOT stenting, or shunt placement before complete repair

Post-operative TOF (initial repair)
- TTE
  - Within 30 days of repair
  - Pre-adolescent Child every 12 months
  - Adolescence every 24 months
  - Every 6 months in an individual with valvular dysfunction other than pulmonary valve, RVOT obstruction, branch pulmonary artery stenosis, arrhythmias, or presence of an RV-to-PA conduit
  - TTE every 3 months if CHF
- Cardiac MR/CT, MRA/CTA Chest every
  - Routine surveillance (36 months) in an individual with PR and preserved ventricular function
  - 12 months if moderate (≥150 mL/m2) or progressive (increase of >25 mL/m2) RV dilatation or dysfunction (RVEF ≤48% or ≥6% decrease in EF) or nearing imaging criteria for PVR.

Post-surgical or catheter based pulmonary valve replacement
- TTE

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

  - Within 30 days follow-up
  - 1 and 6 months after replacement
  - One year post procedure
  - Annually after replacement
  - Every 6 months if RV-to-PA conduit dysfunction, valvular or ventricular dysfunction, branch pulmonary artery stenosis, or arrhythmias
  - Every 3 months if CHF symptoms
- CMR/CT-CMRA/CTA every 2 years

Proprietary Information of UnitedHealthcare.

Double Outlet Right Ventricle (DORV) (PEDCD-2.4.14)

CDP.CHD.2414.A
v1.0.2026

Any surgical status

- TTE, CMR/CT-CMRA/CTA are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Evaluation prior to repair

Unrepaired

- TTE
  - Newborn no limit
  - Monthly infant with balanced systemic and pulmonary circulation
  - Every 3 months child with balanced circulation

Postoperative

- TTE
  - Within 30 days
  - First year post-op every 6 months
  - After one year, TTE every 1 year
  - TTE 3 months in an individual with valvular or ventricular dysfunction, right or left ventricular outflow tract obstruction, branch pulmonary artery stenosis, arrhythmias, or presence of an RV-to-PA conduit, heart failure
- Cardiac MR/CT, MRA/CTA Chest
  - 3 years for asymptomatic individual

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

D-Loop Transposition of the Great Arteries (D-Loop TGA) (PEDCD-2.4.15)

CDP.CHD.2415.A
v1.0.2026

Any surgical status
- **TTE, CMR/CT-CMRA/CTA**, s**tress imaging** are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Any time after procedure involving coronary arteries
- **CMR/CT-CMRA/CTA** every 5 years.

Unrepaired (TTE)
- No Limits

Post arterial switch
- TTE
  - Within 30 days of repair
  - Infant: every one month
  - Child: every 3 months
  - Child with ≥ moderate sequelae: TTE every three 3 months (moderate valvular or ventricular dysfunction, right or left ventricular outflow tract obstruction, branch pulmonary artery stenosis, or arrhythmias
- Routine CMR/CT
  - Every 3 years
  - Every year if neo AI
- MRA/CTA Chest
  - Every 3 years
  - Every year if neo AI or aortic dilation
- Stress imaging
  - 1 routine test after arterial switch at any time

Post Rastelli
- TTE
  - Within 30 days
  - Every three months following procedure for one year

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Pre-adolescent Child Every 6 months following the first year after repair if no or mild sequelae
  - Adolescent annually
  - Every three months if moderate valvular dysfunction, LVOT obstruction, presence of an RV-to-PA conduit, branch, pulmonary artery stenosis, or arrhythmias, or heart failure
- CMR/CT-CMRA/CTA every 3 years

Post atrial switch

- TTE Every 1 year if mild to no symptoms
  - Every 3 months TTE, and CMR MRA CCT CTA if ≥moderate systemic AV, valve regurgitation, systemic RV dysfunction, LVOT obstruction, or arrhythmias, or CHF
  - Routine **CMR/CT-CMRA/CTA** every 3 years

Proprietary Information of UnitedHealthcare.

Congenitally Corrected Transposition of the Great Arteries (ccTGA, LTGA) (PEDCD-2.4.16)

CDP.CHD.2416.A
v1.0.2026

Any surgical status

- TTE, TEE, **CMR/CT-CMRA/CTA** are considered medically necessary for any of the following:
  - Change clinical status and/or new concerning signs or symptoms
  - Preoperative evaluation (typically within one month)
- CMR/CT-CMRA/CTA every 3 years

Unrepaired

- TTE
  - Newborn-Weekly
  - Infant
    - Every 3 months if no cardiac symptoms and only mild findings
    - Every 1 month is cardiac symptoms and moderate findings
  - Child
    - <2 years every 3 months
    - >2 years every 1 year
    - Every 6 months if ≥moderate AV regurgitation
    - Every 3 months if CHF symptoms
  - CMR/CT-CMRA/CTA
    - Every 3 years

Postoperative: Anatomic Repair

- TTE
  - Post–operative evaluation (within 30 days)
  - Every 3 months within a year following repair in an asymptomatic individual with no or mild sequelae
  - Every 1 year after the first year following repair in an asymptomatic individual with no or mild sequelae
  - Every 6 months if valvular or ventricular dysfunction, right or left ventricular outflow tract obstruction, or presence of a RV-to-PA conduit

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Every 3 months if CHF symptoms
- CMR/CT-CMRA/CTA
  - Every 3 years

Postoperative: Physiological Repair with VSD Closure and/or LV-to-PA Conduit

- TTE
  - Postoperative evaluation (within 30 days)
  - Every 3 months within a year following repair in an asymptomatic individual with no or mild sequelae
  - Annually in an asymptomatic individual with no or mild sequelae
  - Every 3 months if in an individual with ≥moderate systemic AV valve regurgitation, systemic RV dysfunction, and/or LV-to-PA conduit dysfunction, or with CHF symptoms
- CMR/CT-CMRA/CTA every 3 months in an individual with ≥moderate systemic AV valve regurgitation, systemic RV dysfunction, and/or LV-to-PA conduit dysfunction, or with CHF symptoms

Truncus Arteriosus (PEDCD-2.4.17)

CDP.CHD.2417.A
v1.0.2026

Any surgical status

- TTE, CMR/CT-CMRA/CTA are considered medically necessary for any of the following:
  - Initial evaluation of change in clinical status and/or new concerning signs or symptoms
  - Prior to planned intervention or surgery

Postoperative

- TTE
  - Within 30 days
  - Monthly in first year after surgery
  - After first year every 6 months
  - Every 3 months if
    - ≥ moderate truncal stenosis or regurgitation
    - Residual VSD or RV to PA conduit or Branch PA obstruction
    - Symptoms of CHF
- CMR/CT-CMRA/CTA
  - Annually if ≥ moderate Truncal stenosis or regurgitation

Proprietary Information of UnitedHealthcare.

Single Ventricle (SV) (PEDCD-2.4.18)

CDP.CHD.2418.A
v1.0.2026

SV references individuals not amenable to biventricular repair, including but not limited to hypoplastic left heart syndrome, tricuspid atresia, Double inlet left ventricle, mitral atresia, unbalanced AVSD, and forms of PA/IVS.

Any surgical status

- Any/All: **TTE, TEE, CMR/CT-CMRA/CTA, and cardiac catheterization** (CPT® 93593, 93594, 93595, or 93597) are considered medically necessary for any of the following:
  - Change clinical status and/or new concerning signs or symptoms
  - Preoperative evaluation (typically within one month)

Unrepaired SV

- TTE allowed one study per week

Stage 1 palliation (TTE)

- Often called Norwood or Sano, or hybrid catheterization procedure
- Routine weekly TTE

Stage 2 palliation (TTE)

- Often referred to as Glenn procedure
- Within 30 days after surgical or catheterization intervention
- 1 per month in infant or child

Stage III, also called Fontan

- TTE within 30 days
- TTE every three months within first post-op year
- Every 6 months after first year
- Every 3 years allow **CMR/CCT-MRA/CTA**
- TTE every 3 months until the finding is stable or there is a need for intervention if there is valvular dysfunction, arrhythmias, heart failure

Surveillance

Cardiac catheterization is considered medically necessary for all Single Ventricles once every 10 years.

Eisenmenger and PHT (with CHD)-(PEDCD-2.4.19)

CDP.CHD.2419.A
v1.0.2026

PHT without CHD is covered in section **Pediatric Pulmonary Hypertension General (PEDCD-7.1)**

These are in addition to studies supported by lesion.

Any surgical status
- TTE, CMR/CT-CMRA/CTA are considered medically necessary for any of the following:
  - Change clinical status and/or new concerning signs or symptoms
  - Preoperative evaluation (typically within one month)

Initial evaluation (TTE)
- Change in clinical status and/or new concerning signs or symptoms
- Before and after PHT therapy

Eisenmenger Syndrome (ES) individual
- TTE every 6 months

PHT associate with CHD
- Unrepaired individuals with evidence of elevated pulmonary vascular resistance can have echocardiograms based on the frequency requested by the provider.
- TTE and Cardiac CMR/CCT for changes in change in pulmonary arterial hypertension-targeted therapy in an individual with postoperative PH
- TTE every 3 months in postoperative stable child with PHT

Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDCD-12)

CDP.CS.0012.A
v1.0.2026

MIS-C Indications for Cardiac Imaging (PEDCD-12.2)

MIS-C Initial Cardiac Imaging (PEDCD-12.2.1)

- When there is concern for MIS-C, as in atypical or incomplete Kawasaki (see **Kawasaki Disease - Acute Phase (PEDCD-6.2)**), echocardiogram (TTE) can be approved
- A cardiac MRI can be approved at the time of diagnosis when there are issues that can affect treatment management not answered by other testing.
- Cardiac CCTA can be done if there is incomplete visualization of the coronary arteries.
- Repeat echocardiograms may be required and approved if either:
  - Treatment decisions will be affected by results (e.g., treating with IVIg).
  - There are new signs or symptoms.

MIS-C Repeat Cardiac Imaging (PEDCD-12.2.2)

The following imaging guidelines reference outpatient management of individuals who have been discharged from the hospital after stability for MIS-C has been established.

- An echocardiogram (TTE) can be approved at the time of presentation and followed by serial echocardiograms (TTE) until stabilization has been achieved for any of the following:
  - New cardiac signs, symptoms, or findings
  - Evidence of recurrence of MIS-C
  - Changes in medication
- Serial echocardiograms can be approved based on the ordering cardiologist's discretion or the treating medical provider in consultation with a cardiologist when there is documented cardiac dysfunction.
- Individuals who are discharged from the hospital after MIS-C and have stable findings can have an echocardiogram (TTE):
  - Within 1 week of discharge
  - 4 weeks post-discharge
  - At 6 months post-discharge
  - One year post-discharge

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Cardiac CCTA can be done if there is incomplete visualization of the coronary arteries.
- A routine cardiac MRI can be done once after 3 months in an individual with evidence of cardiac involvement (e.g., symptoms, EKG, labs, or echocardiogram).
- Individuals with changes, or unanswered questions, on echocardiogram (TTE) may have a Cardiac MRI based on **Cardiac MRI and Cardiac Indications for MRA Chest (CD-5.2)** in the cardiac imaging guidelines.

Individuals with dilated coronary arteries can have imaging based on the AHA Kawasaki guidelines.

AHA risk level	Largest Aneurysm At Any Point	Largest Current Aneurysm	Routine Echocardiogram (TTE)	Routine Stress Imaging	Routine Coronary Imaging
All			All risk levels 4-6 weeks after acute illness		
1	Normal	Normal	One TTE 2-12 months after acute illness	none	none
2	Dilation	Dilation	6 months One year If dilation remains TTE every 2-5 years until resolves	None	None
		Normal	After acute illness: 2-12 months One echocardiogram at one year No echocardiogram after one year		
3.1	Small	Small	6 months 12 months Then yearly	2-3 years	3-5 years

5.4	Large	Normal Or Dilation	1-2 years	2-5 years	none

Symptomatic individuals

- Echocardiogram can be performed at any time with new or progressing cardiac symptoms.
- Stress imaging when there are new or progressing symptoms of ischemia or ventricular dysfunction
- Invasive or coronary imaging coronary angiography (CT, MRI, invasive) when the above studies are positive, inconclusive, or otherwise lead to a conclusion that intervention is needed

Evidence Discussion

SARS-CoV-2 (COVID 19) is usually mild in children. Some children develop a severe inflammatory disease that can present in a similar way to Kawasaki disease or toxic shock syndrome. This syndrome has been defined by the US Centers for Disease Control and Prevention as multisystem inflammatory syndrome in children (MIS-C).

These guidelines are intended for use in the outpatient management of cardiac findings of MIS-C. Additional information can be found in **COVID-19 and Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDHD-12.7)** for the outpatient management of head imaging.

Heart Murmur (PEDCD-3.1)

CDP.CS.003.1.A
v1.0.2026

When evaluating an individual with a murmur for the first time, it will not be known whether the individual has congenital heart disease or not.

Initial pediatric TTE combinations

Cardiologist only submits charges for the procedure actually performed
CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325
CPT® 93303, CPT® 93320, and CPT® 93325
CPT® 93303, CPT® 93306
CPT® 93306 (CPT® 93320 and CPT® 93325 are included with CPT® 93306 and should not be approved separately)

- Any one of the above echocardiography code combinations is considered medically necessary for evaluation of either:
  - Any pathologic murmur
  - Any innocent murmur with associated cardiac signs or symptoms
- Repeat echocardiography is not medically necessary if the initial echocardiogram was normal and the murmur has not changed in quality.

Evidence Discussion

- Heart murmurs are extremely common in pediatric individuals. The thinner chest wall in children allows clearer auscultation of blood flowing through the chambers of the heart, which may result in a murmur on physical exam.
- The majority of murmurs are innocent and do not require further evaluation. More than 30% of children may have an innocent murmur detected during physical examination. Innocent murmurs are typically systolic ejection murmurs with a vibratory or musical quality and generally change in quality when the individual changes position.
- Other types of murmurs can be pathologic and require additional evaluation, usually by a pediatric cardiologist. Echocardiography is considered medically necessary and is performed as part of the office visit.

Chest Pain General (PEDCD-4.1)

CDP.CS.0004.1.A
v1.0.2026

Initial pediatric TTE combinations

Cardiologist only submits charges for the procedure actually performed
CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325
CPT® 93303, CPT® 93320, and CPT® 93325
CPT® 93303, CPT® 93306
CPT® 93306 (CPT® 93320 and CPT® 93325 are included with CPT® 93306 and should not be approved separately)

- Any one of the TTE combinations above is considered medically necessary for pediatric individuals with chest pain and one or more of the following:
  - Exertional chest pain
  - Non-exertional chest pain with abnormal EKG
  - Chest pain with signs or symptoms of pericarditis
  - First-degree relative with sudden unexplained death or cardiomyopathy
  - Recent onset of fever
  - Recent illicit drug use
  - Other signs or symptoms of cardiovascular disease
- Repeat echocardiography is not medically necessary if the initial echocardiogram is normal unless one of the following conditions is present:
  - Increased severity or change in quality of the chest pain
  - New signs or symptoms of cardiovascular disease other than pain
  - New abnormality on EKG
- Cardiac MR or cardiac CT is considered medically necessary for chest pain if prior evaluation suggests:
  - Any coronary artery abnormalities
  - Cardiomyopathy
  - Myocarditis
- Chest MRA or CTA if pulmonary embolism or aortic dissection is suspected
- Stress imaging is considered medically necessary if other imaging suggests coronary artery abnormality, or ETT suggests ischemia. EKG is uninterpretable. Any indication in section **Stress Testing with Imaging (CD-1.4)** in the Cardiac Imaging Guidelines. This can include Stress SPECT, echo or MR.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

Chest pain in pediatric individuals is caused by a cardiac etiology in <5% of cases, yet causes great anxiety for parents resulting in requests for testing.

Individuals with CP may undergo an exercise stress test without imaging.

Echocardiography is performed as part of the office visit. When evaluating an individual for the first time, it will not be known whether the individual has congenital heart disease or not. The cardiologist only submits charges for the procedure actually performed.

Syncope (PEDCD-5.1)

CDP.CS.0005.1.A
v1.0.2026

Initial pediatric TTE combinations

Cardiologist only submits charges for the procedure actually performed
CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325
CPT® 93303, CPT® 93320, and CPT® 93325
CPT® 93303, CPT® 93306
CPT® 93306 (CPT® 93320 and CPT® 93325 are included with CPT® 93306 and should not be approved separately)

- Echocardiography is not medically necessary for most individuals with isolated syncope.
- Echocardiography is considered medically necessary for pediatric individuals with syncope and one or more of the following:
  - Exertional syncope
  - Unexplained post-exertional syncope
  - Abnormal EKG
  - Absence of prodromal symptoms
  - Presence of preceding palpitations within seconds of loss of consciousness
  - Lack of a prolonged upright posture
  - Syncope in response to auditory or emotional
  - First-degree relative with any of the following before age 50:
    - Sudden cardiac arrest or death
    - Pacemaker or implantable defibrillator placement
  - First-degree relative with cardiomyopathy
  - Known congenital heart disease
  - History of Kawasaki disease, or other coronary pathology
  - Pathologic murmur, irregular rhythm, gallop, or click on physical examination
- Repeat echocardiography is not medically necessary if the initial echocardiogram is normal unless one of the following conditions is present:
  - Increased severity or change in quality of the syncope
  - New signs or symptoms of cardiovascular disease other than syncope
  - Family of history of sudden death, cardiomyopathy
  - New abnormality on EKG

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Cardiac MR or Cardiac CT is considered medically necessary for chest pain if prior evaluation suggests any coronary artery abnormalities, cardiomyopathy, myocarditis.
- MRA or CTA Chest if pulmonary embolism or aortic dissection is suspected
- Stress imaging (SPECT, echo or MR) is considered medically necessary (any):
  - If other imaging suggests coronary artery abnormality
  - ETT suggests ischemia
  - EKG is uninterpretable
  - Any indication in section **Stress Testing with Imaging (CD-1.4)** in the Cardiac Imaging Guidelines

Evidence Discussion

Syncope in pediatric individuals is common, with up to 15% of individuals experiencing at least one episode by age 21. Syncope is caused by neurocardiogenic syndrome (vasovagal syncope) in 75% to 80% of cases, which is a benign and self-limiting condition. Despite this, syncope causes great anxiety for parents resulting in requests for testing.

Individuals with CP may undergo an exercise stress test without imaging.

Click Here to Return to the Main TOC

Pediatric Pulmonary Hypertension General (PEDCD-7.1)

CDP.CS.0007.1.A
v1.0.2026

- Pulmonary hypertension in children can be caused by cardiac, pulmonary, or systemic diseases, and idiopathic disease occurs as well.
- Chest x-ray, EKG, and echocardiography (CPT® 93306, or CPT® 93303, with CPT® 93320, and CPT® 93325, see **Transthoracic Echocardiography (TTE) Coding (PEDCD-8.1)** for echocardiography coding considerations) for initial evaluation if pulmonary hypertension is suspected.
- Repeat echocardiography intervals are variable depending on age of individual, etiology, and severity.
  - After a comprehensive initial evaluation, echocardiograms using PH-specific protocols may be performed every 4 to 6 months.
  - Echocardiography is considered medically necessary at any time for new or worsening symptoms or to evaluate a recent change in therapy.
  - Right heart and/or left heart catheterization may be utilized for PAH individuals, including before and after initiation of PH-targeted therapy, and for individuals with concomitant congenital heart disease.
- CT Chest (CPT® 71250) may be medically necessary in addition to CTA Chest (CPT® 71275) or MRA Chest (CPT® 71555) for initial evaluation of all pediatric individuals with pulmonary hypertension to evaluate for pulmonary vascular or interstitial disease, or other intrathoracic causes.
- Cardiac MRI without and with contrast (CPT® 75561) is considered medically necessary for evaluation of inconclusive echocardiogram findings or for monitoring right ventricular function during follow-up.
- Stress echocardiograms may be medically necessary(as in the general cardiac imaging guidelines) see **Stress echo – coding** in the Cardiac Imaging Guidelines.

Evaluation of Pericardial Effusion or Diagnosis of Pericardial Tamponade (PEDCD-9.5)

CDP.CS.0009.5.A
v1.0.2026

- Echocardiogram is the initial imaging study of choice to evaluate pericardial effusions or diagnose pericardial tamponade.
- If a specific clinical question is left unanswered by another recent imaging study, **and** the answer to the clinical question will affect the management of the individual's clinical condition, contrast-enhanced cardiac MRI is useful for evaluating:
  - Pericarditis
  - Neoplastic effusion
  - Tamponade
  - Myocardial infiltration
- Cancers that can metastasize to the pericardium or myocardium and can cause a malignant effusion include lung, breast, renal cell, lymphoma and melanoma.

Kawasaki Disease (PEDCD-6)

CDP.CS.0006.A
v1.0.2026

Kawasaki Disease Initial Imaging (PEDCD-6.1)

- Echocardiography (CPT® 93306) is considered medically necessary for initial assessment for suspected or known Kawasaki disease.
  - Coronary CTA (CPT® 75574), Cardiac MRI without contrast (CPT® 75557), Cardiac MRI without and with contrast (CPT® 75561), or MRA Chest (CPT® 71555) are considered medically necessary for evaluation of inconclusive echocardiogram findings or significant coronary artery abnormalities.
  - Screening of other body areas for aneurysms is not routinely medically necessary in Kawasaki disease, but MRA or CTA (contrast as requested) of the affected body area can be approved for evaluation of signs or symptoms suggesting aneurysm development.
  - See acute and chronic phase for imaging

Background and Supporting Information

- Kawasaki disease (KD) is the leading cause of acquired pediatric cardiac disease in the developed world. It is an acute febrile illness characterized by a medium vessel vasculitis, which predominantly affects the coronary arteries.
  - Individuals who do not fulfill the diagnostic criteria for classic KD may be considered to have incomplete (atypical) KD.
  - If Kawasaki disease is strongly suspected, treatment will often begin even before cardiac evaluation, since early treatment is associated with a lower risk for coronary aneurysm development.

Kawasaki Disease - Acute Phase (PEDCD-6.2)

- Echocardiography is medically necessary when the diagnosis of KD is suspected
  - In uncomplicated presentations, repeat echocardiography is medically necessary at the following intervals after treatment:
    - Within 1 to 2 weeks
    - Within 4 to 6 weeks
  - In presentations with important and evolving coronary artery abnormalities (z-score >2.5) detected during the acute illness, repeat echocardiography (at least twice per

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

week) to monitor for thrombosis is medically necessary until luminal dimensions have stopped progressing.
    - In presentations with expanding large or giant aneurysms, TTE is medically necessary at the following intervals:
        - Twice per week while dimensions are expanding rapidly
        - Once weekly after dimension is stabilized for the first 45 days of illness
        - Then, monthly until the third month after illness onset
- CCTA, or Cardiac MRI, or coronary angiography are considered medically necessary in the acute phase in severe cases to evaluate proximal coronary artery abnormalities when results will impact management decisions.
- Transesophageal echocardiography, Cardiac MRI, and CCTA are not routinely used in the acute phase of illness but are considered medically necessary when **both**:
    - Visualization of the coronary arteries with Transthoracic echocardiography (TTE) is inadequate **and**
    - Results will impact immediate management decisions
- Evaluation of potential aneurysmal involvement in other arterial beds can be assessed with CMRI, CTA, and, rarely, invasive angiography after recovery from the acute illness for individuals with severe coronary artery involvement or symptoms or signs, such as the presence of a pulsatile axillary mass.
- Atypical or incomplete Kawasaki. Echo is considered medically necessary when atypical KD is being considered, may require repeat echocardiograms if treatment decisions will be affected by results (e.g., treating with IVIg), if new signs or symptoms (such as typical peeling) develop.

Evidence Discussion

- The acute phase of Kawasaki disease (KD) can last up to 4-6 weeks from the onset of fever until acute systemic inflammation has resolved and coronary artery dimensions are no longer expanding.
- Based on AHA recommendations, the following classifications are used in risk stratification of coronary artery abnormalities[1]:
    - Z-score classification accounts for the effects of body size and age through use of baseline coronary dimensions adjusted for body surface area. The z-score value represents the number of standard deviation above the mean. (e.g., z=0 pt. has coronary artery dimension value equal to mean, z=2 person has value 2 standard deviation above the mean, based on age, gender, BSA).
    - Coronary Artery Abnormalities Risk Classification based on z-score:
        - 1 - No involvement at any time point (z-score always <2)
        - 2 - Dilation only (z-score 2 to <2.5)

[1] Mccrindle BW, Rowley AH, Newburger JW, et al. Diagnosis, Treatment, and Long-Term Management of Kawasaki Disease: A Scientific Statement for Health Professionals from the American Heart Association. Circulation. 2017;135(17). doi:10.1161/cir.0000000000000484.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - 3 - Small aneurysm (z-score ≥2.5 to <5)
            - 3.1 - Current or persistent
            - 3.2 - Decreased to dilation only or normal luminal dimension
        - 4 - Medium aneurysm (z-score ≥5 to <10, and absolute dimension <8 mm)
            - 4.1 - Current or persistent
            - 4.2 - Decreased to small aneurysm
            - 4.3 - Decreased to dilation only or normal luminal dimension
        - 5 - Large and giant aneurysm (z-score ≥10, or absolute dimension ≥8 mm)
            - 5.1 - Current or persistent
            - 5.2 - Decreased to medium aneurysm
            - 5.3 - Decreased to small aneurysm
            - 5.4 - Decreased to dilation only or normal luminal dimension
    - Additional clinical features that may increase the long-term risk of myocardial ischemia:
        - Greater length and distal location of aneurysms that increase the risk of flow stasis
        - Greater total number of aneurysms
        - Greater number of branches affected
        - Presence of luminal irregularities
        - Abnormal characterization of the vessel walls (calcification, luminal myofibroblastic proliferation)
        - Presence of functional abnormalities (impaired vasodilation, impaired flow reserve)
        - Absence or poor quality of collateral vessels
        - Previous revascularization performed
        - Previous coronary artery thrombosis
        - Previous myocardial infarction
        - Presence of ventricular dysfunction

Kawasaki Disease - Chronic Phase (PEDCD-6.3)

- Long-term management begins at the end of the acute illness, usually at 4 to 6 weeks after fever onset. Management is based on two pieces of data:
    - The dimensions of the largest aneurysm at any point during the disease
    - The dimensions of the largest current aneurysm
- Additional risk factors that may be considered for imaging:
    - Greater length and distal location of aneurysms that increase the risk of flow stasis
    - Greater total number of aneurysms
    - Greater number of branches affected

AHA risk level	Largest Aneurysm At Any Point	Largest Current Aneurysm	Routine Echo	Routine Stress Imaging	Routine Coronary Imaging
5.4	Large	Normal Or Dilation	1-2 years	2-5 years	none

Symptomatic individuals

- Echocardiogram can be performed at any time with new or progressing cardiac symptoms.
- Stress imaging when there are new or progressing symptoms of ischemia or ventricular dysfunction
- Invasive or coronary imaging Coronary angiography (CT, MRI, invasive) when the above studies are positive, inconclusive, or otherwise lead to a conclusion that intervention is needed.

Transthoracic Echocardiography (TTE) Coding (PEDCD-8.1)

CDP.000.8.1.A
v1.0.2026

- CPT® codes for echocardiography are listed in **General Guidelines (PEDCD-1.0)**

Echocardiogram coding notes	CPT®
• The most commonly performed study is a complete transthoracic echocardiogram with spectral and color flow Doppler (CPT® 93306). ◦ CPT® 93306 includes CPT® 93320 and CPT® 93325, so those codes should not be approved along with CPT® 93306.	93306
• Doppler codes (CPT® 93320, CPT® 93321, and CPT® 93325) are add-on codes and are assigned in addition to code for the primary procedure, and should not be approved alone.	+93320 +93321 +93325
• For a 2D transthoracic echocardiogram without Doppler, report CPT® 93307.	93307
• A limited transthoracic echocardiogram is reported with CPT® 93308. ◦ Limited transthoracic echocardiogram should be billed if the report does not “evaluate or document the attempt to evaluate” all of the required structures. ◦ Unlike CPT® 93306, the Doppler CPT® 93321 and CPT® 93325 are not included with CPT® 93308. ◦ CPT® 93321 (not CPT® 93320) should be reported with CPT® 93308 if Doppler is included in the study. ◦ CPT® 93325 should also be reported with CPT® 93308 if color flow Doppler is included in the study.	93308
• For individuals with known congenital heart disease, a limited transthoracic echocardiogram is reported with CPT® 93304, +/- CPT® 93321 and CPT® 93325.	93304

- Providers performing an **initial** echocardiogram on a pediatric individual will not know what procedure codes they will be reporting until the initial study is completed.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- If congenital heart disease is found on the initial echo, a complete echocardiogram is reported with codes CPT® 93303, CPT® 93320, and CPT® 93325 because CPT® 93303 does NOT include Doppler and color flow mapping.
- If no congenital issue is discovered, then CPT® 93306 is reported alone and includes 2-D, Doppler and color flow mapping.

- Since providers may not know the appropriate code(s) that will be reported at the time of the pre-authorization request, they may request multiple codes.
  - The following echocardiography code combinations for any **initial** echocardiogram:
    - CPT® 93303, CPT® 93306, CPT® 93320, and CPT® 93325
    - CPT® 93303, CPT® 93306
    - CPT® 93306
      - CPT® 93320 and CPT® 93325 are included with CPT® 93306 and should not be approved separately.
  - Post-service audits may be completed to ensure proper claims submission.
- Correct coding for subsequent echocardiograms
  - If an individual is being followed for known congenital heart disease, and an echocardiogram is considered medically necessary, the appropriate codes are (CPT® 93303 or 93304) in addition to appropriate doppler codes (CPT® 93320 or 93321) and CPT® 93325.
  - If an individual has documented normal anatomy or acquired heart disease, and an echocardiogram is considered medically necessary, non-congenital codes are appropriate CPT® 93306 (includes all Doppler codes) or CPT® 93308 with CPT® 93321 and CPT® 93325.
  - For individuals with newborn physiology (e.g., ASD versus PFO, or PDA), the final echocardiogram that documents normal anatomy can be coded as congenital. However, any subsequent echocardiograms after that, which would be completed for a new indication, (e.g., shortness of breath) would be coded as non-congenital.

Initial Transthoracic Echocardiography (TTE) Indications (PEDCD-8.2)

CDP.000.8.1.A
v1.0.2026

- In addition to indications listed in previous guideline sections, initial TTE evaluation is considered medically necessary for any of the following:
  - Any signs/symptoms that are possibly cardiac in nature, including (but not limited to) central cyanosis, dyspnea, edema, poor peripheral pulses, feeding difficulty, decreased urine output, hepatomegaly, or desaturation on pulse oximetry.
  - Abnormal EKG or cardiac biomarkers
  - Abnormal chest x-ray suggesting cardiovascular disease
  - First-degree relative with any of the following before age 50:
    - Sudden cardiac arrest or death
    - Pacemaker or implantable defibrillator placement
    - First-degree relative with cardiomyopathy
  - Supraventricular Tachycardia (SVT), Ventricular Tachycardia, or Premature Ventricular Contractions (PVCs)
  - Known or suspected valvular dysfunction
  - Persistent systemic hypertension
  - Individuals with new onset hypertension
    - TTE indicated to assess for cardiac target organ damage (LV mass, geometry, and function) at the time of consideration of pharmacologic treatment of systemic hypertension
  - Obesity (BMI >30) with additional cardiovascular risk factors
  - Stroke
  - Renal failure
  - Preoperative evaluation of individuals with chest wall deformities or scoliosis
  - Known or suspected vascular ring
  - Planned administration of cardiotoxic chemotherapy
    - Generally anthracyclines (doxorubicin, daunorubicin, mitoxantrone, idarubicin, epirubicin)
  - Planned radiation therapy involving heart muscle or hematopoietic stem cell transplant
  - Sickle cell disease or other hemoglobinopathy causing chronic anemia
  - Known or suspected vasculitis, acute rheumatic fever, or other systemic autoimmune disease
  - Aortopathy (such as Marfan, Ehlers-Danlos, Loeys-Dietz)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - Positive personal diagnosis
    - First degree relative
    - Positive gene
    - Finding suggestive of aortopathy such as x-ray showing aortic dilation
  - Muscular dystrophy
    - Positive personal diagnosis
    - First degree relative
    - Positive gene
    - Any findings suggestive of MD, such as neurological exam
  - Cardiomyopathy
    - Diagnosed by other modality (such as cardiac MR)
    - First degree relative
    - Positive genetic testing
    - Findings suggestive of, such as cardiomegaly on x-ray
  - Metabolic, mitochondrial, and storage disorders
    - Positive personal diagnosis
    - First degree relative
    - Positive genetic testing
    - Findings suggestive of on exam or lab findings
  - Abnormalities of cardiac or other viscera situs
  - Signs, symptoms, or blood culture suggestive of endocarditis
  - Known or suspected mass lesion involving the heart or great vessels
  - Known or suspected clot in atrium or ventricle
  - Known or suspected pulmonary hypertension
  - Known or suspected pericardial effusion
  - Complications during prenatal development:
    - Known or suspected cardiovascular abnormality on fetal echocardiogram
    - Maternal phenylketonuria (PKU)
    - Maternal diabetes with no fetal echo
    - Maternal teratogen exposure
    - Maternal infection during pregnancy with potential cardiac sequelae
  - Genetic abnormality known to be associated with cardiovascular disease such as:
    - Down syndrome
    - Turner syndrome
    - 22q11 deletion syndrome
    - Williams syndrome
    - Noonan syndrome
  - First-degree relative family history of:

Repeat Transthoracic Echocardiography Indications (PEDCD-8.3)

CDP.EC.0008.3.A
v1.0.2026

- Repeat echocardiograms may be required for individuals with no new symptoms.
- In addition to indications listed in previous guideline sections, repeat TTE evaluation is considered medically necessary for any of the following:
  - In an individual with known cardiac disease and a previously normal echocardiogram when there is documentation of any of the following:
    - New or worsening cardiac symptoms
    - New EKG abnormality
    - Newly recognized family history suggestive of heritable heart disease
  - In an individual with prior normal evaluation
    - New or worsening symptoms
    - New EKG finding
    - New murmur
    - New finding of inheritable disease in first-degree relative
  - Individuals with first-degree family history of cardiomyopathy (such as, hypertrophic, dilated, arrhythmogenic) or aortopathy
    - Repeat echocardiogram every 12 months
    - Repeat echocardiogram can be done at the additional intervals when the family history or gene mutation is associated with neonatal or fetal disease:
      - At birth
      - Within the first 6 weeks
      - At 3 months
      - At 6 months
      - At one year
      - Then yearly
    - Repeat imaging is **not** medically necessary in individuals with first degree relative with known mutation when **both** of the following apply:
      - Individual has been tested and does not have that mutation
      - Individual has a normal echocardiogram
    - If there are abnormal findings on screening/surveillance imaging, a repeat echocardiogram is allowed to assess stability of findings.
  - Individual with a phenotype positive cardiomyopathy (with or without a positive gene) can be imaged as follows:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Infants (under one year)
  - TTE is considered medically necessary at frequency requested by pediatric cardiology or provider in consultation with pediatric cardiology.
- Children (over one year) yearly testing is considered medically necessary as follows:
  - Repeat TTE every 12 months
  - Repeat TTE to assess stability at discretion of pediatric cardiology, or provider in consultation with pediatric cardiology, after any new or changed clinical finding.
  - TTE at any time with documented new or changing symptoms.

◦ Individual with a known mutation associated with cardiomyopathy or aortopathy and no previous abnormal imaging
- Repeat echocardiogram every 12 months
  - Individuals whose gene mutation is associated with neonatal or fetal disease or there is a family history of neonatal or fetal disease can have repeat echocardiogram at the following intervals:
    - At birth
    - Within the first 6 weeks
    - Then at 3 months
    - At 6 months
    - At one year
    - Then yearly
- If there are abnormal findings on screening/surveillance imaging, a repeat echocardiogram is allowed to assess stability of findings.

◦ Individuals who are status post heart transplant can have echocardiograms repeated as often as requested by heart transplant team.

◦ Every 12 months for individuals receiving active therapy for ventricular hypertrophy, valvular dysfunction, cardiomyopathy
- One time repeat TTE can be approved at 6 months to assess response to a change in therapy

◦ Every 12 months for individuals with chronic pericardial effusions

◦ Every 12 months routine surveillance in asymptomatic individuals with muscular dystrophy (may be replaced by cardiac MRI CPT® 75557 or 75561 at 6 years of life)

◦ Every 12 months for sickle cell disease or other hemoglobinopathy causing chronic anemia and one of the following:
- High-risk genotype (Hgb SS or Sß^0, severe thalassemia, etc.)
- History of acute chest syndrome or intrinsic lung disease
- History of stroke

Proprietary Information of UnitedHealthcare.

    - Receiving chronic transfusion therapy
  - As needed for monitoring cardiotoxicity during chemotherapy administration
  - After completion of chemotherapy and/or radiation therapy. See **Cardiotoxicity and Echocardiography (PEDONC-19.2)** for imaging guidelines.
  - Aortopathies- see **Thoracic Aortic Disease (PEDPVD-4.1)** in the Pediatric Peripheral Vascular Disease Imaging Guidelines
  - TTE follow-up for systemic hypertension
    - Individuals with evidence of end organ damage (Includes LVH, or decreased EF) can have echocardiogram every 6 months until echocardiogram normalizes.
    - Individuals without LV target organ injury (no LVH, normal EF) at initial echocardiographic assessment, repeat echocardiography at yearly intervals may be considered in those with persistent hypertension. (stage 2 HTN, or chronic stage 1 HTN incompletely treated (noncompliance or drug resistance)

CT Heart and Coronary Computed Tomography Angiography (CCTA) General Considerations (PEDCD-10.1)

CDP.CT.0010.1.A
v1.0.2026

- Metal artifact reduces the accuracy of CCTA. Devices that can cause this issue include but are not limited to:
  - Surgical clips
  - Pacemaker devices
  - Defibrillator devices
  - Tissue expanders
- Cardiac testing that does not involve exposure to ionizing radiation should be strongly considered.

Radiation Dose (PEDCD-10.2)

- ACR–NASCI–SPR Practice Parameter for the Performance and Interpretation of Cardiac Computed Tomography (CT) stated, “Cardiac CT should be performed only for a valid medical indication and with the minimum radiation exposure that provides diagnostic image quality.”
- ACR–NASCI–SPR Practice Parameter for the Performance of Quantification of Cardiovascular Computed Tomography (Ct) And Magnetic Resonance Imaging (MRI) stated, “In younger patients, MRI may be the preferred modality, particularly when functional assessment with CT would require retrospective ECG gating and relatively high radiation doses. Further, the use of time-resolved MRA and phase contrast MRI methods offer significant advantages whose relative importance will depend on the specific application.”
  - See table: Practice Estimate of Effective Radiation Dose chart for Selected Imaging Studies in **General Guidelines (PEDCD-1.0)** in the general Cardiac Imaging Guidelines

Indications for CCTA (PEDCD-10.3)

CDP.CT.0010.3.A
v1.0.2026

- In addition to indications listed in previous guideline sections, CCTA is considered medically necessary for any of the following, when a recent TTE and/or MRI is inconclusive:
  - Persistent exertional chest pain and normal stress test
  - Full sibling(s) with history of sudden death syndrome before age 30 or with documented anomalous coronary artery
  - Resuscitated sudden death and contraindication to conventional coronary angiography
  - Unexplained new onset of heart failure if CCTA will replace conventional invasive coronary angiography
  - Documented ventricular tachycardia (6 beat runs or greater) if CCTA will replace conventional invasive coronary angiography
  - Equivocal coronary artery anatomy on conventional cardiac catheterization
  - In infants: otherwise unexplained dyspnea, tachypnea, wheezing, episodic pallor, irritability, sweating, poor feeding, and/or failure to thrive
    - The presence of other congenital heart disease is not a separate indication for CCTA to rule out anomalous coronary artery (except when coronary artery surgery is pending, i.e., Transposition of the great arteries, Tetralogy of Fallot, Truncus arteriosis, aortic root surgery)
  - Evaluation of the arterial supply and venous drainage in children with bronchopulmonary sequestration
- See **Coronary Anomalies (PEDCD-2.4.12)**

Indications for Cardiac CT (CPT® 75572) (PEDCD-10.4)

CDP.CT.0010.4.A
v1.0.2026

- In addition to indications listed in previous guideline sections, CCT is considered medically necessary for any of the following, when a recent TTE and/or MRI is inconclusive:
  - Cardiac or pericardial mass
  - Pericarditis
  - Complications of cardiac surgery or evaluation of post-operative anatomy
  - Cardiac thrombus in individuals with technically limited TTE, TEE, or MRI
  - Clinical suspicion of arrhythmogenic right ventricular dysplasia (ARVD) or arrhythmogenic cardiomyopathy (ARVC)
  - Native aortic abnormalities if echocardiogram is indeterminate
  - Intracardiac anatomy unclear after TTE or CMRI
  - A CTA Chest is medically necessary during a Cardiac CT if there are issues regarding the chest vessels that are inconclusive after echocardiogram or Cardiac MRI

Proprietary Information of UnitedHealthcare.

Indications for Chest CTA with Cardiac CT or CTA (PEDCD-10.5)

CDP.CT.0010.5.A
v1.0.2026

- A Chest CTA may be medically necessary in individuals who require Cardiac CT or Cardiac CTA when:
  - A TTE or MRI is inconclusive for issues regarding chest vasculature
  - Routine imaging is considered medically necessary based on **Imaging and Surveillance per Congenital lesion (PEDCD-2.4)**

Cardiac MRI Coding (PEDCD-9.2)

CDP.MR.0009.2.A
v1.0.2026

Cardiac Imaging Procedure Codes

Cardiac MRI	CPT®
Cardiac magnetic resonance imaging for morphology and function without contrast.	75557
Cardiac magnetic resonance imaging for morphology and function without and with contrast and further sequences.	75561
Cardiac magnetic resonance imaging for morphology and function without contrast; with stress imaging (rarely used in pediatrics).	75559
Cardiac magnetic resonance imaging for morphology and function without and with contrast and further sequences; with stress imaging (rarely used in pediatrics).	75563
Cardiac magnetic resonance imaging for velocity flow mapping (List separately in addition to code for primary procedure).	+75565

- Only one procedure code from the set: CPT® 75557, CPT® 75559, CPT® 75561, and CPT® 75563 should be reported per session.
- Only one flow velocity measurement (CPT® +75565) should be reported per session.

Indications for Cardiac MRI (PEDCD-9.3)

CDP.MR.0009.3.A
v1.0.2026

- In addition to indications listed in previous guideline sections, Cardiac MRI (CPT® 75557 or 75561) evaluation is considered medically necessary for any of the following, when a recent TTE is inconclusive:
  - Assessment of global ventricular function and mass if a specific clinical question is left unanswered by recent TTE and the MRI results will affect management of the individual's condition
  - Individuals with complex congenital heart disease (e.g., Tetralogy of Fallot [TOF], single ventricle, truncus arteriosis, Transposition of the Great Arteries [TGA]) may require a baseline MRI, or routine Cardiac MRI, especially as they approach their teenage years, due to poor imaging windows on echocardiogram, and the need for specific clinical information not seen on prior echocardiograms due to these known limitations. Once these individuals reach age 18, they can be imaged by adult congenital heart disease guideline.
  - Clinical suspicion of arrhythmogenic right ventricular dysplasia (ARVD) or arrhythmogenic cardiomyopathy (ARVC).
  - For pericardial disease (including constrictive pericarditis, restrictive pericarditis, and perimyocarditis), MRI should not be utilized to diagnose pericarditis but only to answer the question regarding possible constriction or restriction suggested clinically or by other techniques (TTE, etc.).
    - MRI without and with contrast (CPT® 75561) is considered the optimal test for this disorder.
  - Evaluate cardiac tumor or mass
    - MRI without and with contrast (CPT® 75561) is considered the optimal test for this disorder.
  - Evaluate anomalous coronary artery
    - MRI without and with contrast (CPT® 75561) or CCTA (CPT® 75574) after echocardiogram is considered the optimal test for this disorder.
  - For Fabry disease, late enhancement MRI may predict the effect of enzyme replacement therapy on myocardial changes that occur with this disease.
    - MRI without and with contrast (CPT® 75561) is considered the preferred test for this disorder.
  - Cardiac MRI (CPT® 75557 or 75561) can be performed to evaluate individuals with congenital cardiomyopathy (muscular dystrophy, glycogen storage disease, fatty acid oxidation disorders, mitochondrial disorders, etc.) or unexplained cases of cardiomyopathy in order to characterize the myocardium.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Cardiac stress perfusion study (CPT® 75559 or CPT® 75563) can be considered on a case by case basis for individuals with any of the following:
  - Anomalous coronary artery
  - Kawasaki disease
  - TGA
  - Ross operation
  - Other disorder with the potential for coronary ischemia
  - Individuals in whom an exercise stress test (EST) without imaging is considered medically necessary but the individual is not able to perform an EST
  - Individuals in whom an exercise stress test (EST) is equivocal, positive, or concern for a false negative
- Assessment of cardiac iron overload such as in hemochromatosis, thalassemia, sickle cell (either CPT® 75557 or CPT® 71550, T2* MRI, contrast not necessary)
  - Screening imaging may be approved every 12 months
  - Imaging may be approved every 3 months for treatment response in individuals receiving active treatment (chelation +/- phlebotomy)
  - Frequently performed along with MRI Abdomen (CPT® 74181) to assess liver iron deposition See **Transfusion-associated (Secondary) Hemochromatosis (PEDAB-18.2)** in the Pediatric Abdomen Imaging Guidelines.

- Asymptomatic individuals with Duchenne Muscular Dystrophy (DMD)
  - MRI Cardiac for DMD **either** CPT® 75557 or CPT® 75561 is considered medically necessary for surveillance if done in place of TTE every year starting at 6 years of age.
  - Female carriers would not typically be imaged until ≥18 years of age and should be imaged according to general Cardiac Imaging Guidelines.
  - CPT® 75565 or CPT® 71555 would not be medically necessary unless there was an independent indication for either of those codes.

Indications for Chest MRA for Congenital Heart Disease (PEDCD-9.4)

CDP.MR.0009.4.A
v1.0.2026

- For Familial Aortopathies, see **Thoracic Aortic Disease (PEDPVD-4.1)** in the Pediatric Peripheral Vascular Disease Imaging Guidelines
- For individuals with known CHD for routine imaging **Imaging and Surveillance per Congenital lesion (PEDCD-2.4)**
- For individuals who have both cardiac and ascending aorta abnormalities (e.g., truncus arteriosus), the following studies may be medically necessary following an inconclusive TTE:
  - Cardiac MRI (CPT® 75557 or CPT® 75561)
  - And MRI Chest (CPT® 71552) or MRA Chest (CPT® 71555) if aorta is involved
- For individuals with aortic abnormalities without cardiac abnormalities (i.e. normal intracardiac anatomy, but coarctation or peripheral pulmonary artery stenosis), the following studies may be medically necessary following an inconclusive TTE:
  - MRI Chest (CPT® 71552)
  - MRA Chest (CPT® 71555)
- MRA Chest (CPT® 71555) is considered medically necessary for individuals with cardiomyopathy or isolated abnormal intracardiac anatomy, when there are inconclusive images on echocardiogram related to chest vessels (e.g. aortic arch, pulmonary arteries, pulmonary veins, systemic veins).

Cardiac Catheterization General Information (PEDCD-11.1)

CDP.DHC.0011.1.A
v1.0.2026

Cardiac Catheterization Procedure Codes

Cardiac Catheterization Procedures	CPT®
Congenital Heart Disease Code “Set”	93593-93597
Right heart catheterization for congenital heart defect(s) including imaging guidance by the proceduralist to advance the catheter to the target zone; normal native connections	93593
Right heart catheterization for congenital heart defect(s) including imaging guidance by the proceduralist to advance the catheter to the target zone; abnormal native connections	93594
Left heart catheterization for congenital heart defect(s) including imaging guidance by the proceduralist to advance the catheter to the target zone, normal or abnormal native connections	93595
Right and left heart catheterization for congenital heart defect(s) including imaging guidance by the proceduralist to advance the catheter to the target zone(s); normal native connections	93596
Right and left heart catheterization for congenital heart defect(s) including imaging guidance by the proceduralist to advance the catheter to the target zone(s); abnormal native connections	93597
Anomalous coronary arteries, patent foramen ovale, mitral valve prolapse, and bicuspid aortic valve	93451-93464, 93566-93568
RHC without LHC or coronaries	93451
LHC without RHC or coronaries	93452

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Cardiac Catheterization Procedures	CPT®
RHC and retrograde LHC without coronaries	93453
Native coronary artery catheterization;	93454
with bypass grafts	93455
with RHC	93456
with RHC and bypass grafts	93457
with LHC	93458
with LHC and bypass grafts	93459
with RHC and LHC	93460
with RHC and LHC and bypass grafts	93461
LHC by trans-septal or apical puncture	+93462
Angiography of noncoronary arteries and veins performed as a distinct service	Select appropriate codes from the Radiology and Vascular Injection Procedures sections.
CPT® 93593 to 93597 are appropriate for invasive evaluation of congenital heart disease	

- These guidelines apply to individuals with stable conditions and who are not in the acute setting. Individuals in acute settings or with unstable angina should be handled as medical emergencies.
- Pediatric catheterization is done for many purposes, including diagnosis and intervention of congenital and acquired heart disease.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- When device placement is planned (ASD/VSD device, transcatheter valve implantation, PDA device), the procedure codes for those devices include all cardiac catheterization(s), intraprocedural contrast injection(s), fluoroscopic radiological supervision and interpretation, and imaging guidance performed to complete the procedure. A diagnostic catheterization may be considered on a case-by-case basis if there are unanswered issues via noninvasive imaging.
- A right heart catheterization can be approved for pulmonary artery interventions (e.g., stents, coils).

Click Here to Return to the Main TOC

Cardiac Catheterization Indications (PEDCD-11.2)

CDP.DHC.0011.2.A
v1.0.2026

- Diagnostic catheterization is considered medically necessary:
  - When other advanced imaging has failed to resolve a clinical issue and results will impact the individual's management
    - For example, a catheterization to assess ventricular pressures and shunt to determine if VSD surgery is required
  - For preoperative assessment in complex heart disease
    - Norwood procedure
    - Bidirectional Glenn shunt
    - Fontan procedure
    - Pulmonary atresia
  - Pulmonary hypertension
  - During some interventions such as:
    - Valvuloplasty
    - Pulmonary artery or vein stents
  - Assessment of individuals who are status post heart transplant
  - See **Kawasaki Disease Initial Imaging (PEDCD-6.1)** for specific intervals in Kawasaki Disease
  - On an individual who is having a device placed when:
    - A diagnostic catheterization, or stenting is needed in addition to the device
    - The diagnostic catheterization is considered medically necessary separate from the device placement
  - Individuals with anomalous coronary arteries, or with syndromes associated with abnormal coronary arteries (i.e., Williams syndrome) or acquired CAD (i.e., KD see **Kawasaki Disease Initial Imaging (PEDCD-6.1)**
    - When diagnostic images are not adequate or evaluation or treatment decision
    - Preoperative for cardiac surgery
    - New symptoms concerning for ischemia

General Guidelines (PEDNECK-1.0)

NKP.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination, since the onset or change in symptoms, and appropriate laboratory studies should be performed prior to considering advanced imaging (CT, MRI, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled follow-up imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the neck is not medically necessary. Advanced imaging of the neck is only medically necessary in individuals who have documented active clinical signs or symptoms of disease involving the neck.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the neck are not medically necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Age Considerations (PEDNECK-1.1)

NKP.GG.0001.1.A

v1.0.2026

- Many conditions affecting the neck in the pediatric population have different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, minor differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals who are 18 years old or younger should be imaged according to the Pediatric Neck Imaging Guidelines. Any conditions not specifically discussed in the Pediatric Neck Imaging Guidelines should be imaged according to the General Neck Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Neck Imaging Guidelines, except where directed otherwise by a specific guideline section.

Proprietary Information of UnitedHealthcare.

Modality General Considerations (PEDNECK-1.3)

NKP.GG.0001.3.A
v1.0.2026

- MRI
  - MRI Orbit/Face/Neck is generally performed without and with contrast (CPT® 70543) unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, sedation is usually required for almost all infants (except neonates) and young children (age <7 years) as well as older children with developmental delays. Sedation may be administered by oral, intravenous, and/or inhalational routes. In order to limit sedation time in this subdivision of pediatric individuals, the following should be considered:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access is medically necessary for sedation and there is no contraindication for using contrast, imaging without and with contrast may avoid repeating a study with sedation to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If studies of multiple body areas are medically necessary by these clinical guidelines for the clinical condition being evaluated, MRI studies of all necessary body areas should be obtained concurrently in the same sedation session.
  - The presence of surgical hardware or implanted devices may preclude the use of MRI.
  - Coordination between provider and the imaging service can result in providing the best choice of radiologic studies for the pediatric individual.
- CT
  - CT Neck typically extends from the base of the skull to the upper thorax.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - A separate CPT® code for head imaging in order to visualize the skull base is not medically necessary.
        - In some cases, especially in follow-up of a known finding, it is medically necessary to limit the exam to the region of concern to reduce radiation exposure.
    - CT Neck is generally performed with contrast (CPT® 70491) unless the individual has a documented contraindication to CT contrast or otherwise stated in a specific guideline section.
    - CT Neck may be medically necessary for further evaluation of abnormalities suggested on prior US or MRI Procedures.
    - In general, CT Neck is medically necessary when evaluating trauma, malignancy, and for preoperative planning.
    - CTA Neck (CPT® 70498) is medically necessary for evaluation of the vessels of the neck, especially with concern for dissection.
    - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
    - Coordination between the provider and the imaging service can result in the best choice of radiologic studies for the pediatric individual.
- Ultrasound
    - Ultrasound soft tissues of the neck (CPT® 76536) is medically necessary as an initial study for evaluating thyroid, parathyroid, parotid and other salivary gland lesions. Ultrasound is also used to further characterize adenopathy, palpable superficial masses, or swelling.
    - For those individuals who do require additional advanced imaging after ultrasound, ultrasound can be very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the pediatric individual.
- Nuclear Medicine
    - Nuclear medicine studies of the neck in pediatric individuals are most commonly used to evaluate neck masses, or thyroid and parathyroid disease following initial studies with anatomic imaging, such as ultrasound, CT, or MRI. See **Neck Masses (Pediatric) (PEDNECK-2.1)** and **Thyroid and Parathyroid (PEDNECK-6)** for imaging guidelines.
    - Evaluation of salivary gland function in individuals with dry mouth (xerostomia) and **ONE** of the following:
        - Sjögren syndrome **OR**
        - Sialadenitis **OR**
        - History of head or neck radiation therapy, one of the following is medically necessary:
            - Salivary Gland Nuclear Imaging (CPT® 78230) **OR**

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

  - Salivary Gland Nuclear Imaging with Serial Imaging (CPT® 78231) **OR**
  - Salivary Gland Function Study (CPT® 78232)
- 3D Rendering
  - 3D Rendering indications in pediatric neck imaging are identical to those in the general imaging guidelines. See **3D Rendering (Preface-4.1)** in the Preface Imaging Guidelines.

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Neck Masses (Pediatric) (PEDNECK-2.1)

NKP.NM.0002.1.A
v1.0.2026

- Evaluation of neck masses in pediatric individuals involves careful consideration of clinical history and accurate physical examination. The individual's age and knowledge of the anatomy and common lesions of the neck are very important in narrowing the differential diagnosis.
- Congenital lesions (vascular lesions, thyroglossal duct cysts, branchial cleft cysts, teratomas, dermoids, and thymic cysts) and lymphadenopathy account for nearly all benign neck lesions. Primary malignant tumors in children are usually neuroblastoma, lymphoma, or rhabdomyosarcoma.
- Initial imaging of choice:
  - Ultrasound Neck (CPT® 76536)
    - Color Doppler ultrasound bilateral study of carotid arteries (CPT® 93880) **OR** Duplex unilateral study (CPT® 93882) is medically necessary to evaluate the vasculature.
- For inconclusive ultrasound or to further delineate abnormalities on ultrasound:
  - MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) **OR**
  - CT Neck with contrast (CPT® 70491)
- For concern for malignancy:
  - Ultrasound Neck is not medically necessary prior to imaging.
  - MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) **OR**
  - CT Neck with contrast (CPT® 70491)
- For lymphadenopathy persisting for more than 4-weeks of treatment **OR** suspicion of complications such as abscess formation:
  - Ultrasound Neck (CPT® 76536) is medically necessary. See **Cervical Lymphadenopathy (PEDNECK-3.1)**.
- Congenital cervical cysts:
  - Ultrasound Neck (CPT® 76536) is medically necessary for suspected cystic neck mass.
- Congenital cervical sinus, fistula, cyst, or for preoperative planning:
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) **OR**
  - CT Neck with contrast (CPT® 70491)
    - For fourth branchial cleft cyst/sinus/fistula- barium swallow is medically necessary in addition to the above conventional imaging.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Salivary gland nuclear imaging: **ONE** of the following is medically necessary for evaluation of parotid masses to allow preoperative diagnosis of Warthin's tumor:
  - Salivary Gland Nuclear Imaging (CPT® 78230) **OR**
  - Salivary Gland Nuclear Imaging with Serial Imaging (CPT® 78231) **OR**
  - Salivary Gland Function Study (CPT® 78232)
- Ranula (a cystic structure on the floor of the mouth):
  - CT Neck with contrast (CPT®70491) **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary, especially when there is concern for a "plunging" ranula (lesion extending into the submandibular space).

Background and Supporting Information

- Cervical lymphadenitis is common in children and follows most viral or bacterial infections of the ears, nose, and throat. No advanced imaging is necessary with uncomplicated lymph node enlargement.
- Congenital cervical cysts frequently present in children and include thyroglossal duct cyst (55% of cases), cystic hygroma (25%), branchial cleft cysts (16%), bronchogenic cyst (0.91%), and thymic cyst (0.3%).
- The most common malignant neck tumors in children are lymphoma, rhabdomyosarcoma, and neuroblastoma. Many neuroblastomas arise in the neck.

Differential Diagnosis of Neck Lesions by Anatomic Region:

- Subcutaneous tissues:
  - Teratoma (includes dermoid cysts)
    - Cervical teratomas are typically large bulky masses discovered at birth or in the first year of life.
    - Large lesions may cause stridor, dyspnea, or dysphagia.
    - Most teratomas arise in the anterior suprahyoid neck and may be midline or off midline in location and adjacent to or within a thyroid lobe.
  - Vascular lesions
  - Lipoma
  - Cellulitis
  - Plexiform neurofibromas
  - Keloid
  - Scar
  - Pilomatrixoma
  - Subcutaneous fat fibrosis (in neonates)
- Retropharyngeal space:
  - Abscess, cellulitis, adenitis
    - Usually involves children under age 6.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - Individuals have history of upper respiratory tract infection followed by high fever, dysphagia, and neck pain.
    - Lymphadenopathy
    - Extension of goiter
    - Extension of pharyngeal tumor
- Retrovisceral space (posterior to the cervical esophagus):
    - Gastrointestinal duplication cysts (usually are diagnosed in first year of life).
- Pretracheal space (contains trachea, larynx, cervical esophagus, recurrent laryngeal nerves, and thyroid and parathyroid glands):
    - Thyroglossal duct cyst
        - Thyroglossal duct cyst most commonly presents before the age of 20; 75% present as a midline mass and 43% of individuals present with an infected mass.
        - Usually presents as an enlarging, painless midline mass.
        - Thyroid carcinoma occurs in 1% of thyroglossal duct cysts.
    - Goiter
    - Laryngocele
    - Lymphadenopathy
    - Teratoma
    - Abscess
    - Ectopic thymus or cervical extension of normal thymus
- Danger space (closed space lying between the skull base and the posterior mediastinum and between the alar and prevertebral fasciae in a sagittal plane):
    - Cellulitis
    - Abscess
- Prevertebral space:
    - Neurenteric cyst
    - Cellulitis
    - Abscess
    - Spondylodiskitis
    - Lymphadenopathy
    - Paraganglioma
- Carotid sheath space:
    - Jugular vein thrombosis or phlebitis
    - Lymphadenopathy
    - Cellulitis
    - Abscess
    - Paraganglioma
- Parotid gland space:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Parotid lymphadenopathy
- Retromandibular vein thrombosis
- Parotiditis
- Sialodochitis (inflammation of the salivary gland duct)
- Salivary duct stone
- Abscess

- Submandibular and sublingual spaces:
  - Cellulitis
  - Abscess
  - Sialadenitis
  - Thyroglossal duct cyst
  - Branchial cleft cyst
    - 90% of branchial abnormalities arise from the second branchial apparatus.
    - Second branchial cleft cysts are the most common branchial cleft cyst and usually present in individuals between 10 and 40 years as painless fluctuant masses.
    - They typically present as slowly growing, non-tender masses in the upper neck.
    - Most second branchial cleft cysts are located in the submandibular space, at the anteromedial border of the sternocleidomastoid muscle, lateral to the carotid space, or posterior to the submandibular gland.
    - Ranula – typically cystic masses in the floor of the mouth
- Masticator space (includes masseter and pterygoid muscles):
  - Venous or lymphatic malformation
  - Cellulitis
  - Abscess
  - Rhabdomyosarcoma
- Parapharyngeal space:
  - Cellulitis
  - Abscess
  - Neurogenic tumors (CN V, IX, XI and XII)
  - Paragangliomas
  - Neurofibromas
  - Lymphoma
  - Rhabdomyosarcoma
- Paravertebral space:
  - Cervical dermal sinus (epithelium lined dural tubes that connect the skin with the central nervous system or its covering)
  - Meningocele
  - Rhabdomyosarcoma

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Lymphoma
- Neuroblastoma
- Neurofibroma

- Posterior cervical space:
  - Lymphadenopathy
  - Lymphatic malformation

Congenital Neck Masses:

- Anterior neck masses
  - Branchial anomolies
    - Sinus: with either an internal (to the pharynx) or external (to the skin) opening
    - Fistula: with both an internal and external opening
    - Cyst: closed sac with no openings
  - First branchial anomalies
    - Typically sinus or cyst
    - Located anywhere from the external auditory canal to the region of the parotid gland, down to the level of the hyoid; may communicate with the preauricular soft tissue/parotid, parapharyngeal space or anterior triangle of the neck
      - Type I tract parallels the external auditory meatus.
      - Type II tract courses over the angle of mandible through the parotid ending near/within the external auditory canal bony cartilaginous junction.
  - Second branchial anomalies
    - The most common
    - Located from anterior neck in the region of the middle to lower two thirds of the sternocleidomastoid and the great vessels to the pharyngeal mucosa (tonsil)- a tract and/or cyst may occur anywhere along this path
  - Third branchial anomalies
    - Typically located from the low anterior neck to the base of the pyriform sinus
  - Fourth branchial anomalies
    - Potential tract from the low anterior neck to the thyroid gland or mediastinum
  - Cervical thymus
    - Ectopic thymic remnants can be found in the anterior neck (left more commonly than right) and extend deep (near the carotid sheath)- can connect to mediastinum or have cystic components.
- Midline
  - Ectopic Thyroid/Thyroglossal Duct Cysts
    - Anywhere from the tongue base to the mediastinum (a result of the normal embryologic pathway of the thyroid that fails to obliterate or reach its normal location in the lower neck)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Just off the midline
  - Thyroid/Thyroglossal Duct Cysts (cysts below the hyoid bone may be lateral to the midline in position)
    - Laryngocele
      - An abnormal dilation of the saccule of the larynx
        - Internal: within the thyroid cartilage
        - External: beyond the thyrohyoid membrane into the neck
- Anywhere within the neck
  - Teratomas
    - Tissue from all three germ cell layers (ectodermal, mesodermal and endodermal components) typically present as a firm mass, can have calcifications seen on imaging
  - Dermoid cysts
    - Cysts with ectodermal and mesodermal structures (commonly lined by epidermis and containing epidermal appendages) typically in the midline/ submental region, but can be anywhere in the head and neck including orbit
  - Epidermoid cysts
    - Cysts with only ectodermal components (with squamous material)
  - Pilomatixoma
    - Lesion derived from hair matrix/follicles
  - Vascular anomalies
    - Hemangiomas (most common)
      - Congenital: present at birth typically involute
      - Infantile: noted to have a rapid/proliferative phase followed by involution
    - High flow
      - Arteriovenous malformations (AVM) and arteriovenous fistuas (AVF) tangle of vessels
    - Low flow
      - Venous lymphatic and capillary malformations
  - Lymphatic malformations (lymphangiomas)
    - Result from a failure of lymph spaces to connect to the rest of the lymphatic system
      - Macrocystic: comprised of large cysts
      - Microcystic: comprised of smaller cysts typically more infiltrative, lending to difficult excision

Evidence Discussion

- Ultrasound, although operator dependent, is utilized for the initial evaluation of pediatric neck masses, secondary to its availability, expense, lack of radiation, and

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

avoidance of sedation.[1] Ultrasound is limited by poor depth of penetration when evaluating deeper abnormalities.[2]

- Contrast enhanced CT is easily accessible and available; however, it exposes the individual to ionizing radiation.[1]
- MRI provides excellent soft tissue detail without radiation; however, due to the time needed for complete imaging, anesthesia or sedation may be required.[1] Children under 6 years of age, children with developmental delays, or children with anxiety/ claustrophobia may require deep sedation in order to successfully perform a complete radiologic study.[3]

Imaging (PEDNECK-3.1)

NKP.CL.0003.1.A
v1.0.2026

- Painful acute lymphadenopathy and other painful neck masses (including neck "swelling") should be treated with a trial of conservative therapy for at least 4-weeks, including antibiotics if appropriate.
  - If there is improvement with conservative treatment, advanced imaging is not medically necessary.
  - Ultrasound (CPT® 76536) is medically necessary for any of the following:
    - Initial evaluation of persistent lymphadenopathy following 4-weeks of treatment/ observation **OR**
    - Unexplained fever (temperature ≥100.4°F) and there is clinical concern for suppurative lymphadenopathy/neck abscess
- For inconclusive ultrasound/to further characterize abnormalities found on ultrasound:
  - MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) **OR**
  - CT Neck with contrast (CPT® 70491)
- If systemic symptoms or other clinical findings suggest malignancy, see **Pediatric Lymphomas (PEDONC-5)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Background and Supporting Information

- Both MRI and CT are superior to ultrasound for defining the relationship of an abscess to adjacent structures, particularly the airway, and for detecting posterior cervical, mediastinal and intracranial extension.
- Inflammatory lymph nodes from acute lymphadenitis are usually painful, tender, and mobile, frequently associated with upper respiratory infection, pharyngitis or dental infection.
- Occasionally, sarcoidosis or toxoplasmosis and human immunodeficiency virus (HIV) can cause inflammatory lymphadenopathy as well.

Evidence Discussion

- Ultrasound can be used not only as an initial imaging modality, but also as a tool for serial examinations in cases without pathologic features.[1]
- Ultrasound has the benefit of being able to be used to serially evaluate the pediatric individual with cervical adenopathy without the need for sedation/anesthesia and without exposure to radiation.[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Both CT and MRI can provide additional information that may assist with surgical planning. CT is low risk, but involves radiation exposure, while MRI does not involve radiation, but requires more time to complete the study and possibly sedation.[1]

Dystonia/Torticollis (PEDNECK-4.1)

NKP.TO.0004.1.A
v1.0.2026

Infants under 12 Months of Age (Congenital Muscular Torticollis/Fibromatosis Colli)

- Ultrasound Neck (CPT® 76536) is medically necessary as the initial study.
  - If Ultrasound is Positive→ No further imaging is medically necessary as the diagnosis is defined.
  - If Ultrasound is Negative or to further evaluate for other structural causes:
    - CT Neck with contrast (CPT® 70491) **OR**
    - MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR**
    - MRI Orbit/Face/Neck without and with contrast (CPT® 70543)

Background and Supporting Information

- Individuals usually present by 2-weeks of life with an anterior neck mass, which is commonly right sided (75% of cases). A history of a traumatic breech or forceps delivery is common.
- Congenital muscular torticollis is more common in male infants.

Children and Adults (Acquired Torticollis)

- Initial evaluation with history of trauma, and low suspicion of injury:
  - Plain radiographs of the cervical spine are medically necessary
    - To identify fracture or malalignment if plain radiographs are inconclusive or in individuals with a high-risk mechanism of cervical spine injury within the last 3 months (see below**):
      - CT Neck with contrast (CPT® 70491) **AND/OR**
      - CT Cervical Spine without contrast (CPT® 72125) is medically necessary.
- In the clinical setting of cervical spine trauma with an associated neurologic deficit:
  - MRI Cervical Spine without contrast (CPT® 72141) is medically necessary.
- In the absence of trauma, to identify underlying abscess, bony, muscular, vascular, or neurologic causes, ONE of the following is medically necessary:
  - CT Neck with contrast (CPT® 70491), **OR**
  - CT Cervical Spine without contrast (CPT® 72125), **OR**
  - MRI Cervical Spine without contrast (CPT® 72141), **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543), **OR**
  - MRA Neck without and with contrast (CPT® 70549)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - Positive→ Further advanced imaging is not medically necessary if a local cause has been identified.
  - Negative→ MRI Brain without and with contrast (CPT® 70553) is medically necessary to exclude CNS cause.

**High-risk mechanisms of cervical spine injury may include:

- Head trauma and/or maxillofacial trauma
- Pedestrian in a motor vehicle accident
- Fall from above standing height
- Diving accident
- Head-on motor vehicle collision without/with airbag deployment
- Rollover motor vehicle collision
- Ejection from the vehicle in a motor vehicle collision
- High speed of the vehicle at the time of collision
- Not wearing a seatbelt/shoulder harness in a motor vehicle collision
- Individuals with ankylosing spondylitis are at high-risk of cervical spine fractures even with minor direct/indirect trauma to the cervical spine which can result in quadriparesis/quadriplegia

Background and Supporting Information

- Injury or inflammation involving the sternocleidomastoid or trapezius muscles is the most common cause of acquired torticollis in children.
- Torticollis or cervical dystonia is an abnormal twisting of the neck in which the head is rotated or twisted. Acute causes are most common. Children with deep space neck infections present with torticollis approximately 50% of the time. Other causes are variable and may be congenital, acquired (caused by trauma, juvenile idiopathic arthritis, or neoplasm), or idiopathic.

Evidence Discussion

- Ultrasound is the initial method of evaluation of suspected fibromatosis colli. Ultrasound has a sensitivity of 100% and has the advantages of being readily available as well as avoiding sedation and radiation.[1]
- Standard x-rays are the initial imaging modality after trauma, but can be technically challenging due to head position.[2,3]
- Both CT and MRI assist in diagnosing non traumatic torticollis as a result of atlantoaxial subluxation; CT has the advantage of being readily available; however, it exposes the child to radiation, while MRI provides better soft tissue detail such as spinal cord compression, but may require sedation/anesthesia due to the length of the study.[3]

Dysphagia (PEDNECK-5.1)

NKP.DY.0005.1.A

v1.0.2026

- Dysphagia imaging indications in pediatric individuals are very similar to those for adult individuals. See **Dysphagia and Upper Digestive Tract Disorders (Neck-3.1)** in the Neck Imaging Guidelines.
- For concern of foreign body ingestion as the etiology of dysphagia initial imaging:
  - X-rays of the neck and chest are medically necessary.
- For dysphagia associated with chest pain and difficulty swallowing both solids and liquids or gastroesphageal reflux:
  - Esophageal motility study (CPT® 78258) is medically necessary.
- For a suspected anatomical variant such as a vascular ring, right sided aortic arch, or double arch noted on chest radiography (which can be associated with dysphagia):
  - CTA Chest (CPT® 71275) **OR**
  - MRA Chest (CPT® 71555) is medically necessary.

Evidence Discussion

- X-rays are medically necessary as the initial evaluation of foreign body ingestion in children. Plain films provide the advantage of being readily available to detect radiopaque foreign bodies or other pathologic findings.[1]
- Chest CT and MRI provide information regarding anatomy and possible external compression resulting in dysphagia, but require the use of contrast and possible sedation.[1]

Thyroid Masses or Nodules (PEDNECK-6.1)

NKP.PT.0006.1.A

v1.0.2026

- For the initial study for evaluation of thyroid masses, diffuse thyroid enlargement, or nodules in pediatric individuals:
  - Ultrasound Neck (CPT® 76536) is medically necessary.
- **For a normal or elevated TSH** with any solitary or suspicious thyroid nodule noted on imaging or physical exam:
  - Fine needle aspiration (FNA) under ultrasound guidance (CPT® 76942) is medically necessary.
- **For a low TSH:**
  - Nuclear thyroid scintigraphy (either CPT® 78013 or CPT® 78014) is medically necessary.
    - Hyperfunctioning nodules should be treated surgically but may also undergo FNA under ultrasound guidance (CPT® 76942) if suspicious in appearance and not being treated surgically.
    - Hypofunctioning nodules should undergo FNA under ultrasound guidance (CPT® 76942).
- For lymph node assessment if cervical lymph node imaging was not performed at the time of the initial diagnostic thyroid ultrasound:
  - Repeat imaging with Ultrasound Neck (CPT® 76536) is medically necessary.
- For preoperative planning in individuals with large or fixed masses, vocal cord paralysis, or bulky cervical or supraclavicular adenopathy:
  - CT Neck without contrast (CPT® 70490) **OR**
  - CT Neck with contrast (CPT® 70491) **OR**
  - MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary.
  - In addition, for individuals with substernal extension of the thyroid, pulmonary symptoms or abnormalities on chest x-ray:
    - CT Chest without contrast (CPT® 71250) **OR**
    - CT Chest with contrast (CPT® 71260) is medically necessary.
- If any biopsy reveals thyroid carcinoma, See **Thyroid Cancer (ONC-6)** in the Oncology Imaging Guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Repeat ultrasound (CPT® 76536) and/or FNA under ultrasound guidance (CPT® 76942) is medically necessary 3-6 months following initial biopsy if the initial biopsy shows inadequate, or non-diagnostic findings.
  - Repeat ultrasound (CPT® 76536) is medically necessary in 6-12 months if the nodule is stable and/or FNA is benign.
  - The nodule should be treated surgically if growing or the FNA is not benign.
- Repeat ultrasound (CPT® 76536) is medically necessary 6-12 months following initial biopsy if the initial biopsy shows benign findings.
  - Repeat ultrasound (CPT® 76536) is medically necessary every 1-2 years if the nodule is stable.
  - Repeat FNA under ultrasound guidance (CPT® 76942) or manage surgically if the nodule is growing or concerning new findings are present.
  - Benign nodules that have been surgically resected do not require routine imaging follow up in the absence of clinical or laboratory changes suggesting recurrence.
- If the initial biopsy shows indeterminate or suspicious findings, surgery is recommended.

Evidence Discussion

- Ultrasound is used as the initial evaluation for thyroid abnormalities and follow up as it is noninvasive, radiation free, inexpensive, very sensitive, and does not require sedation to complete.[1,2,25,26]
- Fine needle biopsy in pediatric thyroid nodules has a sensitivity of 94% and specificity of 100%.[3]
- Both CT and MRI can be valuable in preoperative evaluation of thyroid disease for determining involvement of lymph nodes or adjacent structures. However, iodine based contrasts can lead to suppression of radioactive iodine thyroid uptake, thus postponing radioiodine treatment and favoring the use of MRI.[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Hyperthyroidism (PEDNECK-6.2)

NKP.PT.0006.2.A
v1.0.2026

- For the initial study for evaluation of hyperthyroidism:
  - Ultrasound Neck (CPT® 76536) is medically necessary.
    - If a nodule or mass is discovered on ultrasound, the individual should be imaged according to **Thyroid Masses or Nodules (PEDNECK-6.1)**.
- For all other individuals with documented hyperthyroidism:
  - Thyroid uptake nuclear imaging (either CPT® 78012 or CPT® 78014) is medically necessary.

Background and Supporting Information

- Common causes are Graves' disease and autoimmune disorders (lupus, rheumatoid arthritis, and Sjögren syndrome).

Evidence Discussion

- Ultrasound is used as the initial evaluation for thyroid abnormalities and follow up as it is noninvasive, radiation free, inexpensive, very sensitive, and does not require sedation to complete.[1,2]
- The use of a radioactive iodine uptake scan (although involves ionizing radiation exposure) is medically necessary if the diagnosis is unclear after ultrasound and laboratory evaluation have been completed.[4,5]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Hypothyroidism (PEDNECK-6.3)

NKP.PT.0006.3.A

v1.0.2026

- For the initial study for evaluation of hypothyroidism:
  - Ultrasound Neck (CPT® 76536) is medically necessary.
    - If a nodule or mass is discovered on ultrasound, the individual should be imaged according to **Thyroid Masses or Nodules (PEDNECK-6.1)**.
- For individuals with documented congenital hypothyroidism, thyroid uptake nuclear imaging (either CPT® 78012 or CPT® 78014) is medically necessary.

Background and Supporting Information

- Causes of pediatric hypothyroidism include thyroid congenital dysgenesis, dyshormonogenesis autoimmune thyroiditis, Hashimoto thyroiditis, subacute thyroiditis, and abnormality in the pituitary gland or hypothalamus. Congenital hypothyroidism is usually diagnosed in the neonate on a routine perinatal screening examination.

Evidence Discussion

- Ultrasound is used as the initial evaluation for thyroid abnormalities and follow up as it is noninvasive, radiation free, inexpensive, very sensitive, and does not require sedation to complete.[1,2]
- The use of a radioactive iodine uptake scan (although involves ionizing radiation exposure) is medically necessary if the diagnosis is unclear after ultrasound and laboratory evaluation have been completed.[4,5]

Esophagus (PEDNECK-7.1)

NKP.ES.0007.1.A

v1.0.2026

- Esophagus imaging indications in pediatric individuals are very similar to those for adult individuals. See **Dysphagia and Upper Digestive Tract Disorders (Neck-3.1)** in the Neck Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - For suspected foreign body ingestion or impaction:
    - Plain x-rays are medically necessary for initial imaging.
    - Ultrasound Neck (CPT® 76536) is medically necessary for evaluation of upper esophageal foreign bodies.
    - See **Dysphagia and Upper Digestive Tract Disorders (Neck-3.1)**.
  - For evaluating congenital atresia with associated tracheoesophageal fistula:
    - Esophagram is medically necessary.
  - For evaluation of suspected congenital malformations with inconclusive x-rays or esophagram:
    - CT Neck with contrast (CPT® 70491) **AND/OR**
    - CT Chest with contrast (CPT® 71260)
      - 3D rendering (CPT® 76376 or CPT® 76377) is medically necessary for preoperative planning in complex cases.
  - Plain radiographs alone usually suffice for the diagnosis of esophageal atresia and a contrast examination of the esophagus is not warranted but may be medically necessary for post-operative evaluation.

Evidence Discussion

- The initial evaluation for possible foreign body ingestion is plain x-rays, because of their availability and affordability.[1,8]
- Esophagram, in the setting of esophageal atresia with tracheoesophageal fistula, allows for diagnosis of the condition through the use of a nasogastric tube being withdrawn while instilling contrast material.[1]
- Chest x-ray is used as the initial evaluation of the mediastinum when concerns are present for a congenital abnormality because of availability and affordability.[1] Evaluation of vascular ring or sling includes an esophagram. For further evaluation, CT is favored over MRI secondary to availability, expedited time, and cost.[2,3]

Trachea (PEDNECK-8.1)

NKP.TR.0008.1.A

v1.0.2026

- Trachea imaging indications in pediatric individuals are similar to those for adult individuals. See **Imaging of the Larynx, Trachea, and Bronchus (Neck-9.1)** in the Neck Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - For evaluation of suspected congenital malformations if x-rays are inconclusive:
    - CT Neck with contrast (CPT® 70491) **AND/OR**
    - CT Chest with contrast (CPT® 71260) are medically necessary.
      - If requested, 3D rendering (CPT® 76376 or CPT® 76377) is medically necessary for preoperative planning in complex cases.
  - CT Chest (either without contrast CPT® 71250 or with contrast CPT® 71260) is medically necessary in complicated cases or when bronchoscopy is being considered.

Evidence Discussion

- Chest x-ray, because of its availability and affordability, is generally regarded as the initial imaging study in evaluating possible foreign body aspiration. Chest x-ray has a sensitivity of 62-88% and a specificity of 30-97% of detecting airway foreign bodies.[1,2,12]
- CT may play a role in diagnosing foreign body aspiration in children with non-specific complaints such as fever and cough. CT of the chest has greater than 92% sensitivity and specificity and a diagnostic accuracy of 98% in detecting airway foreign bodies and can play a role in the individual with an unclear or atypical clinical picture.[1,10,11]
- Chest x-ray is used as the initial evaluation of the mediastinum when concerns are present for a congenital abnormality. For further evaluation, CT is favored over MRI secondary to availability, expedited time, and cost.[4]

General Guidelines (PEDONC-1.0)

ONCP.GG.0001.0.A

v2.0.2026

- A relevant clinical evaluation or meaningful contact (telephone call, electronic mail or messaging) should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled off therapy surveillance evaluation or cancer screening. The clinical evaluation may include a relevant history and physical examination, including biopsy, appropriate laboratory studies, and results of non-advanced or advanced imaging modalities.
  - Because of the relatively small number of childhood cancer treatment centers, it is common to combine off-therapy visits with imaging and other sub-specialist visits to accommodate families traveling long distances for their child's care.
- Unless otherwise stated in the disease-specific guideline, a histological confirmation of malignancy (or recurrence) and the stage of disease is required to perform a medical necessity review of the requested imaging.
- Unless otherwise stated in the disease-specific guideline, advanced imaging of asymptomatic individuals is not routinely medically necessary without signs or symptoms of systemic involvement of cancer.
- Conventional imaging performed prior to diagnosis should not be repeated unless there is a delay of at least 6 weeks since previous imaging and treatment initiation or there are new or significantly worsening clinical signs or symptoms
- Generally, the studies listed in the disease-specific sections reflect the studies supported by current literature and research for that condition. If a study is not listed, then it is not medically necessary.
- Routine imaging of brain, spine, neck, chest, abdomen, pelvis, bones, or other body areas is not medically necessary except where explicitly stated in a diagnosis-specific guideline section, or if one of the following applies:
  - Known prior disease involving the requested body area
  - New or worsening symptoms or physical exam findings involving the requested body area (including non-specific findings such as ascites or pleural effusion)
  - New finding on basic imaging study such as plain x-ray or ultrasound
  - New finding on adjacent body area CT/MRI study (i.e., pleural effusion observed on CT abdomen)
  - Unless otherwise stated in the disease-specific guideline, advanced imaging of asymptomatic individuals is not routinely supported without signs or symptoms of systemic involvement of cancer.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Repeat imaging studies are not generally medically necessary unless there is evidence of disease progression, recurrence of disease, and/or the repeat imaging will affect an individual's clinical management.

- Unless otherwise stated in the diagnosis-specific guidelines, imaging for treatment response is medically necessary after every 2 cycles, which is usually ~6 weeks of therapy for solid tumors and usually ~8 to 12 weeks for CNS tumors
- Unless otherwise specified for a specific cancer type, once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET is not medically necessary for continued disease monitoring or surveillance unless one of the following applies:
  - Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence
  - Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging
  - PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance

Clarification of phases of therapy

Phases of Oncology Imaging	Definition
Screening	• Imaging requested for individuals at increased risk for a particular cancer in the absence of known clinical signs or symptoms • Screening using advancing imaging is only supported for conditions listed in **Screening Imaging in Cancer Predisposition Syndromes (PEDONC-2)**
Suspected/Initial Staging	• All imaging studies requested from the time cancer is first clinically suspected until the initiation of specific treatment ◦ CT Chest prior to anesthesia for biopsy or resection of solid tumors and CTs of other involved body areas are generally indicated and should be performed concurrently ◦ Metastatic CNS imaging and nuclear medicine imaging are generally deferred until after a histologic diagnosis is made, unless otherwise indicated by diagnosis-specific guideline

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Phases of Oncology Imaging	Definition
Treatment Response	• Imaging performed during any type of active treatment (chemotherapy or other medications, radiation therapy, or surgery), including evaluation at the end of planned active treatment ◦ Unless otherwise stated in the diagnosis-specific guidelines, imaging for treatment response is medically necessary after every 2 cycles, which is usually ~6 weeks of therapy for solid tumors and usually ~8 to 12 weeks for CNS tumors
Surveillance	• Imaging performed in individuals who are asymptomatic or have chronic stable symptoms and not receiving any active treatment, even if residual imaging abnormalities are present ◦ PET imaging is not medically necessary for surveillance imaging unless specifically stated elsewhere in the diagnosis-specific guideline sections
Recurrence	• All imaging studies completed at the time a recurrence or progression of a known cancer is strongly suspected or documented based on clinical signs or symptoms, laboratory findings, or results of basic imaging studies such as plain radiography or ultrasound • Following documented recurrence of childhood cancer, any studies recommended for initial staging of that cancer type in the diagnosis-specific imaging guideline section should be approved ◦ During active treatment for recurrent pediatric cancer, conventional imaging evaluation (CT or MRI, should use the same modality for ongoing monitoring as much as possible) of previously involved areas is medically necessary according to the treatment response imaging in the diagnosis-specific guideline section ▪ Always refer to the diagnosis specific guideline for PET indications in recurrence.

- Brain imaging is performed for signs or symptoms of brain disease.
  - MRI Brain without and with contrast (CPT® 70553) is the medically necessary study for evaluation of suspected or known brain metastases. If a non-contrast CT head shows suspicious lesion, MRI Brain is medically necessary to further characterize the lesion.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- CT Head without and with contrast (CPT® 70470) is medically necessary when MRI is contraindicated or not available, or if there is skull bone involvement.
- Certain malignancies including, but not limited to, melanoma, lung cancer, and renal cell cancer have indications for brain imaging for asymptomatic individuals,
- If stage IV disease is demonstrated elsewhere or if systemic disease progression is noted, refer to disease specific guidelines
- Initiation of angiogenesis therapy is not an indication for advanced imaging of the brain in asymptomatic individuals (Avastin/Bevacizumab; <3% risk of bleeding and <1% risk of serious bleeding)

- Bone Scan:
  - Primarily used for evaluation of bone metastases in individuals with solid malignancies.
  - Indications for bone scan in individuals with history of malignancy include – bone pain, rising tumor markers, elevated alkaline phosphatase, or in individuals with primary bone tumor.
  - For evaluation of suspected or known bony metastases, CPT® 78306 (Nuclear bone scan whole-body) is medically necessary.
  - Radiopharmaceutical Localization scan SPECT (CPT® 78803 or CPT® 78831) or SPECT/CT (CPT® 78830 or CPT® 78832) is medically necessary as an add-on test for further evaluation of a specific area of interest.
  - CPT® codes 78300 (Nuclear bone scan limited), 78305 (Nuclear bone scan multiple areas), or 78315 do not have any indications in oncology nuclear medicine imaging.
- Bone scan supplemented by plain x-rays are the initial imaging modalities for suspected malignant bone pain. For specific imaging indications, see also:
  - **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)**
  - **Bone (Non-Vertebral) Metastases (ONC-31.5)**
  - **Spinal/Vertebral Metastases (ONC-31.6)**
  - **Carcinoma of Unknown Primary Site (ONC-31.7)**
- Delay PET/CT for at least 12 weeks after completion of radiation treatment, unless required sooner for imminent surgical resection.
- PET/CT may be considered prior to biopsy in order to determine a more favorable site for biopsy when a prior biopsy was nondiagnostic or a relatively inaccessible site is contemplated which would require invasive surgical intervention for biopsy attempt.
- PET/CT may be indicated if:
  - Conventional imaging (CT, MRI, or bone scan) reveals findings that are inconclusive or negative, with continued suspicion for recurrence
- **Unless specified in diagnosis-specific guideline section PET/CT Imaging is NOT medically necessary for**:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Infection, inflammation, trauma, post-operative healing, granulomatous disease, rheumatological conditions
- Concomitantly with separate diagnostic CT studies
- Conclusive evidence of distant or diffuse metastatic disease on recent conventional imaging studies
- Metastatic disease in the central nervous system (CNS)
- Lesions less than 8 mm in size
- Follow up after localized therapy (i.e., radiofrequency ablation, embolization, stereotactic radiation, etc.)
- Rare malignancies, due to lack of available evidence regarding the diagnostic accuracy of PET in rare cancers
- Surveillance
  - Serial monitoring of individuals who are not currently receiving anti-tumor treatment or are receiving maintenance treatment
  - Serial monitoring of FDG avidity until resolution.
  - PET/CT avidity in a residual mass at the end of planned therapy is not an indication for PET/CT imaging during surveillance.
  - Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging

- Please refer to general guidelines section **PET Imaging in Oncology (ONC-1.4)** and **PET Imaging in Pediatric Oncology (PEDONC-1.4)** for further guidance regarding PET. Those guidelines should be applied with regard to radiotracer coverage.
- Please refer to general guidelines in **Unlisted Procedure Codes in Oncology (ONC-1.5)** for unlisted procedures in pediatric oncology.

Clinical Trials

- Similar to investigational and experimental studies, clinical trial imaging requests will be considered to determine whether they meet these evidence-based guidelines.
- Imaging studies which are inconsistent with established clinical standards, or are requested for data collection and not used in direct clinical management are not medically necessary.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence;

Age Considerations (PEDONC-1.1)

ONCP.GG.0001.1.A

v2.0.2026

- The majority of malignancies occurring in the pediatric population are different diagnoses than those occurring in the adult population.
- For those diseases which occur in both pediatric and adult populations, minor differences may exist in management between pediatric and adult medical oncologists due to the following:
  - Age of the individual
  - Comorbidities
  - Differences in disease natural history between children and adults

AGE APPROPRIATE GUIDELINES	
Age of Individual	**Appropriate Imaging Guidelines**
≥18 years old at initial diagnosis	• General Oncology Imaging Guidelines, except where directed otherwise by a specific guideline section
<18 years old at initial diagnosis	• Pediatric Oncology Imaging Guidelines, except where directed otherwise by a specific guideline section
15 to 39 years old at initial diagnosis (defined as Adolescent and Young Adult (AYA) oncology individuals)	• When unique guidelines for a specific cancer type exist only in either Oncology or Pediatric Oncology, AYA individuals should be imaged according to the guideline section for their specific cancer type, regardless of the individual's age • When unique guidelines for a specific cancer type exist in both Oncology and Pediatric Oncology, AYA individuals should be imaged according to the age rule in the previous bullet

Click Here to Return to the Main TOC

Appropriate Clinical Evaluations (PEDONC-1.2)

ONCP.GG.0001.2.A
v2.0.2026

- The majority of pediatric oncology imaging indications are listed in the diagnosis-specific guideline sections
  - Rare malignancies and other circumstances not specifically addressed elsewhere in the Pediatric Oncology guidelines, the following general principles apply:
    - Routine imaging of brain, spine, neck, chest, abdomen, pelvis, bones, or other body areas is not medically necessary in the absence of:
      - Localizing symptoms or
      - Abnormalities on plain radiography or ultrasound
- The overwhelming majority of pediatric oncology individuals treated in the United States will be enrolled on or treated according to recent Children's Oncology Group (COG) protocols
  - COG is a National Cancer Institute (NCI) supported clinical trials group
  - These imaging guidelines are generally consistent with evaluations recommended by COG protocols commonly used for direct individual care (whether formally enrolled on study or not)
    - Requests for exception to guidelines based on COG protocol should be accompanied by the COG road map or COG details in the medical record for case-by-case consideration.
  - For individuals enrolled in a COG study, imaging recommended by COG protocols is generally medically necessary unless the imaging is being performed solely to address a study objective and would not be indicated in usual clinical care.
    - Requests for exception to guidelines based on COG protocol should be accompanied by the COG road map or COG details in the medical record for case-by-case consideration.

Phases of Pediatric Oncology Imaging:

- Pediatric malignancies, in general, behave more aggressively than adult cancers, and the time from initial suspicion of cancer to specific therapy initiation can be measured in hours to days for most pediatric cancers
- It is recommended that children with pediatric solid tumors undergo CT evaluation of the chest prior to general anesthesia for biopsy or resection due to the risk of post-operative atelectasis mimicking pulmonary metastasis resulting in inaccurate staging and/or delay in therapy initiation

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Unlike adult cancers, in most pediatric cancers surveillance does not begin until all planned multi-modal therapy is completed
- Pediatric cancers where surgical resection is considered curative are listed in the diagnosis-specific guideline sections
- Certain tumor types do not require surveillance with advanced imaging as individual outcomes following relapse are not improved by surveillance imaging. See diagnosis-specific guideline sections for details
- Imaging may be indicated more frequently than recommended by guidelines with clinical documentation that the imaging results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance

Phases of Oncology Imaging	Definition
Screening	• Imaging requested for individuals at increased risk for a particular cancer in the absence of known clinical signs or symptoms • Screening using advancing imaging is only supported for conditions listed in **Screening Imaging in Cancer Predisposition Syndromes (PEDONC-2)**
Suspected/Initial Staging	• All imaging studies requested from the time cancer is first clinically suspected until the initiation of specific treatment ◦ CT Chest prior to anesthesia for biopsy or resection of solid tumors and CTs of other involved body areas are generally indicated and should be performed concurrently ◦ Metastatic CNS imaging and nuclear medicine imaging are generally deferred until after a histologic diagnosis is made, unless otherwise indicated by diagnosis-specific guideline
Treatment Response	• Imaging performed during any type of active treatment (chemotherapy or other medications, radiation therapy, or surgery), including evaluation at the end of planned active treatment ◦ Unless otherwise stated in the diagnosis-specific guidelines, imaging for treatment response is medically necessary after every 2 cycles, which is usually ~6 weeks of therapy for solid tumors and usually ~8 to 12 weeks for CNS tumors

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Phases of Oncology Imaging	Definition
Surveillance	• Imaging performed in individuals who are asymptomatic or have chronic stable symptoms and not receiving any active treatment, even if residual imaging abnormalities are present ◦ PET imaging is not medically necessary for surveillance imaging unless specifically stated in elsewhere in the diagnosis-specific guideline sections
Recurrence	• All imaging studies completed at the time a recurrence or progression of a known cancer is strongly suspected or documented based on clinical signs or symptoms, laboratory findings, or results of basic imaging studies such as plain radiography or ultrasound • Following documented recurrence of childhood cancer, any studies recommended for initial staging of that cancer type in the diagnosis-specific imaging guideline section should be approved ◦ During active treatment for recurrent pediatric cancer, conventional imaging evaluation (CT or MRI, should use the same modality for ongoing monitoring as much as possible) of previously involved areas is medically necessary according to the treatment response imaging in the diagnosis-specific guideline section ▪ Always refer to the diagnosis specific guideline for PET indications in recurrence.

Radiation Treatment Planning In Pediatric Oncology

- Imaging performed in support of radiation therapy treatment planning should follow guidelines outlined in **Unlisted Procedure Codes in Oncology (ONC-1.5).**

Cardiac Function Assessment in Pediatric Oncology During Active Treatment:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
• Evaluation of cardiac function prior to cardiotoxic chemotherapy, and for monitoring while on active therapy or at end of therapy at the discretion of the treating pediatric oncologist based on: ◦ Cumulative cardiotoxic therapy received to date ◦ Individual's age and gender ◦ Most recent echocardiogram results ◦ New or worsening cardiac symptoms	• Echocardiography (CPT® 93306, CPT® 93307, or CPT® 93308)
• For either of the following: ◦ Echocardiography yielded a borderline shortening fraction (<30%) and additional left ventricular function data are necessary to make a chemotherapy decision OR ◦ Echocardiography windowing is suboptimal due to body habitus or tumor location	• Multi-gated acquisition (MUGA, CPT® 78472) blood pool nuclear medicine scanning

Background and Supporting Information

Immunosuppression During Pediatric Cancer Therapy and Imaging Ramifications:

- Individuals may be severely immunocompromised during active chemotherapy treatment and any conventional imaging request to evaluate for infectious complications during this time frame should be approved immediately
  - Imaging requests for infectious disease concerns for all individuals with absolute neutrophil count (ANC) <500 **or**
  - Inconclusive findings on chest x-ray or US at any ANC during active treatment should be approved as requested
  - Individuals may have therapy-induced hypogammaglobulinemia which requires supplemental intravenous immune globulin (IVIG) during maintenance therapy. These individuals receiving supplemental IVIG should be treated similarly to individuals with ANC <500 with regards to imaging for infectious disease

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Some individuals are treated with very intensive chemotherapy regimens (including autologous stem cell transplantation) and spend the majority of their chemotherapy treatment phase in the hospital. See: **Hematopoietic Stem Cell Transplantation (ONC-29).**
- Due to the high risk of invasive infections, frequent CT may be indicated to evaluate known sites of invasive fungal infection, and in general these should be approved as requested
  - Surveillance imaging of asymptomatic individuals to detect invasive fungal infection has not been shown to impact individual outcomes
    - Imaging requests are indicated when acute clinical decisions will be made based on the imaging

Hematopoietic Stem Cell Transplant (HSCT) in Pediatric Oncology:

- Transplantation of hematopoietic stem cells from bone marrow, peripheral blood, or cord blood is commonly used in the following clinical situations:
  - High-risk or recurrent leukemia (allogeneic)
  - Recurrent lymphoma (allogeneic or autologous)
  - Hemophagocytic lymphohistiocytosis (allogeneic)
  - High-risk sickle cell disease (allogeneic)
  - High-risk neuroblastoma (autologous)
  - High-risk CNS tumors (autologous)
  - Recurrent Ewing sarcoma family of tumors (autologous, rarely allogeneic)
- Imaging considerations for HSCT should follow guidelines in: **Hematopoietic Stem Cell Transplantation (ONC-29).**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Modality General Considerations (PEDONC-1.3)

- Plain radiography
  - Chest x-ray (CXR) can provide a prompt means to evaluate primary intrathoracic tumors and continues to be the initial imaging study recommended to detect complications, such as suspected infection, in symptomatic individuals undergoing treatment.
  - CXR continues to be the initial imaging study recommended for pulmonary surveillance for some pediatric cancers. See diagnosis-specific guideline sections for details.
  - Plain radiography continues to be the initial imaging study recommended for evaluation of lesions involving the appendicular skeleton, both during and after completion of treatment. See diagnosis-specific guideline sections for details.
  - Plain abdominal radiographs have largely been replaced by ultrasound, CT, or MRI.
- Ultrasound
  - Ultrasound is not widely used in pediatric oncology for staging but is frequently used for surveillance in individuals who have successfully treated (primarily abdominal or pelvic) tumors with little or no residual disease.
  - See diagnosis-specific guideline sections for details.
- CT
  - CT with contrast is the imaging study of choice in pediatric individuals with lymphomas or solid tumors of the neck, thorax, abdomen, and/or pelvis
    - If CT contrast use is contraindicated due to allergy or impaired renal function, either CT without contrast or MRI without and with contrast may be substituted at the discretion of the ordering physician
- MRI
  - MRI without and with contrast is the study of choice for CNS tumors and musculoskeletal tumors
    - If MRI contrast use is contraindicated due to allergy or impaired renal function, MRI without contrast may be substituted at the discretion of the ordering physician
  - Due to the length of time for image acquisition and the need for stillness, anesthesia is required for almost all infants and young children (age <7 years), as well as older children with delays in development or maturity. In this population, MRI imaging sessions should be planned with a goal of avoiding a short-interval

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

repeat anesthesia exposure due to insufficient information using the following considerations:

- MRI should generally be performed without and with contrast unless there is a specific contraindication to gadolinium use since the individual already has intravenous access for anesthesia
  - Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast
  - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAS) use is not warranted at this time
  - It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAS should be assessed
  - If requesting clinicians indicate that a non-contrast study is being requested due to concerns regarding the use of gadolinium, the exam can be approved

◦ In some instances, to reduce time under anesthesia for MRI in pediatric individuals, surveillance or restaging studies may be requested with contrast only when it is determined that repeat non-contrast imaging does not add to an individual clinical case. These may be approved on a case-by-case basis.

- If multiple body areas are supported by these guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session

• Nuclear medicine

◦ General PET imaging consideration can be found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**.

◦ Bone scan is frequently used for evaluation of bone metastases in pediatric oncology during initial treatment, treatment response, and surveillance

- CPT® 78315 has no specific indications for evaluation of malignant disease

◦ ^{123}I-metaiodobenzylguanidine (MIBG) scintigraphy is the preferred metabolic imaging for neuroblastoma and is positive in 90% to 95% of neuroblastomas. MIBG is also used for evaluation of pheochromocytomas, paragangliomas, ganglioneuromas, and ganglioneuroblatomas, PET/CT indications are provided in the relevant sections.

PET Imaging in Pediatric Oncology (PEDONC-1.4)

ONCP.GG.0001.4.A
v2.0.2026

Throughout these guidelines, unless otherwise specified, the term "PET" refers specifically to ^{18}F-FDG-PET imaging and also applies to PET/CT fusion studies.

- PET imaging in pediatric oncology should use PET/CT fusion imaging (CPT® 78815 or CPT® 78816)
- The decision whether to use skull base to mid-femur ("eyes to thighs") procedure code for PET (CPT® 78815) or whole-body PET (CPT® 78816) is addressed in the diagnosis-specific guideline sections.
- PET imaging in oncology should use PET/CT fusion imaging (CPT® 78815 or CPT® 78816)
- PET/MRI is generally not supported for a vast majority of oncologic conditions due to lack of standardization in imaging technique and interpretation. However, it is medically necessary in select circumstances when all of the following criteria are met:
  - The individual meets condition-specific guidelines for PET/MRI OR
  - The individual meets ALL of the following:
    - The individual meets guideline criteria for PET/CT, AND
    - PET/CT is not available at the treating institution, AND
    - The provider requests PET/MRI in lieu of PET/CT
  - When the above criteria are met, PET/MRI is medically necessary using the code combination of PET Whole-Body (CPT® 78813) and MRI Unlisted (CPT® 76498). All other methods of reporting PET/MRI are inappropriate.
    - When clinically appropriate, diagnostic MRI codes may be medically necessaryat the same time as the PET/MRI code combination.
- Unbundling PET/CT imaging into separate PET (such as CPT® 78812 or CPT® 78813) and diagnostic CT codes is otherwise not medically necessary.
- PET imaging is not reliable for the detection of anatomic lesions smaller than 8 mm in size.
- Delay PET/CT for at least 12 weeks after completion of radiation treatment, unless required sooner for imminent surgical resection.
- PET imaging using isotopes other than ^{18}F-FDG, ^{68}Ga-DOTATATE, or ^{68}Ga-DOTATOC is considered not medically necessary at this time.
- PET has not been shown to be diagnostically useful in all forms of childhood cancer. PET is medically necessary for pediatric malignancies with significant published

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

evidence regarding its diagnostic accuracy and importance in accurately directing individual care decisions. See diagnosis-specific guideline sections for details.

- PET imaging is not specific to cancer and has a high rate of false positivity. Inflammation, infection (especially granulomatous), trauma, and post-operative healing may show high levels of FDG uptake and be false-positive for malignant lesions.
- PET for rare malignancies not specifically addressed by these guidelines is generally not medically necessary due to lack of available evidence regarding diagnostic accuracy of PET in the majority of rare cancers. Conventional imaging studies should be used for initial staging and treatment response for these diagnoses.
- PET is medically necessary if **all** of the following apply:
  - Conventional imaging (CT, MRI, US, plain film) reveals findings that are equivocal or suspicious
  - No other specific metabolic imaging (MIBG, octreotide, technetium, etc.) Is appropriate for the cancer type
  - The submitted clinical information describes a specific decision regarding the individual's care that will be made based on the PET results
- PET imaging for surveillance imaging **only** when specifically stated elsewhere in the diagnosis-specific guideline sections
- Unless otherwise specified for a specific cancer type, once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET is not medically necessary for continued disease monitoring or surveillance unless **one** of the following applies:
  - Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence
    - Residual mass that has not changed in size since the last conventional imaging does **not** justify PET imaging
    - PET avidity in a residual mass at the end of planned therapy is **not** an indication for PET imaging during surveillance.
  - Very rare circumstances where tumor markers or obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities
  - The individual is undergoing salvage treatment for a recurrent solid tumor with residual measurable disease on conventional imaging and confirmed repeat negative PET imaging will allow the individual to transition from active treatment to surveillance

Diagnostic Radiation Exposure in Pediatric Oncology (PEDONC-1.5)

ONCP.GG.0001.5.A

v2.0.2026

- Young children are presumed to be at increased risk for malignancy from diagnostic radiation exposure, most commonly from CT and nuclear medicine imaging. They are more sensitive to radiation than adults and generally live longer after receiving radiation doses from medical procedures, resulting in a larger number of years during which to manifest a cancer.
- Because of this presumed increased risk in young children, requests to substitute MRI without and with contrast for CT with contrast to avoid radiation exposure are medically necessary if ALL of the following criteria apply:
  - The individual is presently a young child and the ordering physician has documented the reason for MRI, rather than CT, is to avoid radiation exposure.
  - The disease-specific guidelines do not list CT as superior to MRI for the current disease and time point, meaning the MRI will provide equivalent or superior information relative to CT.
  - The request is for a body area other than Chest as MRI is substantially inferior to CT for detection of small pulmonary metastases.
- The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Screening Imaging in Cancer Predisposition Syndromes – General Considerations (PEDONC-2.1)

ONCP.SC.0002.1.A

v2.0.2026

- This section is intended to give guidance for screening imaging prior to diagnosis with a specific malignancy. Once an individual with a cancer predisposition syndrome has been diagnosed with a malignant disease, future imaging decisions should be guided by the appropriate disease-specific guidelines except as explicitly stated elsewhere in this section.
- This section's guidelines are limited to cancer predisposition syndromes with screening imaging considerations. Syndromes requiring only clinical or laboratory screening are not discussed here.
- In general, a relevant detailed history and physical examination and appropriate laboratory studies should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled screening evaluation identified in this section.
- Where MRI is indicated in these guidelines, CT may be approved only if MRI is contraindicated, given the risk of radiation exposure in these syndromes.
- Many of these cancer predisposition syndromes also affect adults as survival continues to improve for these individuals.
  - Adults with syndromes covered in this section may follow these imaging guidelines except where contradicted by specific statements in the general imaging guidelines.
- Documentation of genetic or molecular confirmation of the appropriate syndrome with increased cancer risk is preferred for any individual to qualify for screening imaging. There are a number of complex ethical, social, and financial issues involved in the decision to complete genetic testing in a pediatric individual.
  - From the 2013 AAP Policy Statement, "Predictive genetic testing for adult-onset conditions generally should be deferred unless an intervention initiated in childhood may reduce morbidity or mortality." **Imaging surveillance is one such intervention and should not be performed without justifiable cause**.
  - Genetic testing should be performed in conjunction with genetic counseling for appropriate communication of risks identified by testing.
  - When genetic testing is not possible, formal diagnosis after evaluation by a physician with significant training and/or experience in cancer predisposition

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

syndromes (most commonly a geneticist or oncologist) is generally sufficient to confirm eligibility for screening imaging.

- Due to the length of time for image acquisition and the need for stillness, anesthesia is required for almost all infants and young children (age < 7 years), as well as older children with delays in development or maturity. In this individual population, MRI imaging sessions should be planned with a goal of avoiding a short-interval repeat anesthesia exposure due to insufficient information using the following considerations:
  - MRI should always be performed without and with contrast unless there is a specific contraindication to gadolinium use since the individual already has intravenous access for anesthesia.
    - Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
    - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If requesting clinicians indicate that a non-contrast study is being requested due to concerns regarding the use of gadolinium, the exam can be approved.
    - In some instances, to reduce time under anesthesia for MRI in pediatric individuals, surveillance or restaging studies may be requested with contrast only when it is determined that repeat non-contrast imaging does not add to an individual clinical case. These may be approved on a case-by-case basis.
  - If multiple body areas are supported by these guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session

Li-Fraumeni Syndrome (LFS) (PEDONC-2.2)

ONCP.SC.0002.2.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with LFS:

Indication	Medically Necessary Imaging Study
All individuals	• BOTH of the following, annually: ◦ MRI Brain without and with contrast (CPT® 70553) ◦ Whole-body MRI (WBMRI, CPT® 76498) ▪ CPT® 76498 is the only code for whole-body MRI at this time. • Every 3 months from birth: ◦ Abdominal (CPT® 76700) and pelvic (CPT® 76856) ultrasound • Beginning at age 20: ◦ Annual Breast MRI (CPT® 77049), alternating every 6 months with breast ultrasound, in addition to the previously noted annual MRI studies.
Documented signs or symptoms suggestive of possible malignancy	• Targeted MRI without and with contrast of the involved body area(s)

Background and Supporting Information

- LFS - syndrome inherited in an autosomal dominant manner (50% risk to offspring) associated with germline mutations in *TP53* resulted in an increased susceptibility to a variety of cancers.
  - Eighty percent of individuals will have germline *TP53* mutation:
    - Tumor-specific *TP53* mutations are much more common than germline *TP53* mutations and are not associated with an increased risk for subsequent cancers.
    - If *TP53*-negative, formal diagnosis of LFS should be assigned by a physician with significant training and/or experience in LFS (most commonly a geneticist or oncologist) based on specified clinical criteria prior to beginning a screening imaging program.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - *TP53* mutations may be present in 50% to 80% of pediatric adrenocortical carcinoma, 10% of pediatric rhabdomyosarcoma, and 10% of pediatric osteosarcoma.
- Individuals with LFS have an increased sensitivity to ionizing radiation, so screening strategies resulting in significant radiation exposure are not appropriate (CT and nuclear medicine).
- When a specific malignancy is suspected, the individual should be imaged according to the imaging guideline specific to the suspected cancer type.
- Annual complete detailed physical examinations, complete blood counts, and urinalyses form the backbone of LFS cancer screening.

Neurofibromatosis 1 and 2 (NF1 and NF2) (PEDONC-2.3)

ONCP.SC.0002.3.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with NF1:

Indication	Medically Necessary Imaging Study
• Clarification of the diagnosis of NF1 if evaluation by a physician with significant training and/or experience in neurofibromatosis is inconclusive ◦ Most commonly a neurologist, geneticist, ophthalmologist, or oncologist	• One-time MRI Brain (CPT® 70553) and Orbits (CPT® 70543) without and with contrast
• New or worsening neurological or visual symptoms	• MRI Brain (CPT® 70553) and Orbits (CPT® 70543) without and with contrast
• Clinical symptoms suggestive of change in a known plexiform neurofibroma ◦ Examples include: pain, rapid growth, and neurologic dysfunction	• MRI without and with contrast
• Clinical symptoms concerning for malignant transformation of a known plexiform neurofibroma, and ALL of the following are met: ◦ Recent MRI is inconclusive regarding transformation or progression ◦ Negative PET will result in a decision to avoid biopsy in a difficult or morbid location	• PET/CT (CPT® 78815 or 78816)
• Baseline tumor burden at age 16 or older (one-time imaging)	• WBMBRI (CPT® 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• New soft tissue mass(es)	• See: Soft tissue mass information in **Soft Tissue Mass and Morton's Neuroma (MS 10.1)** in the Musculoskeletal Imaging Guidelines or **Soft Tissue and Bone Masses – General Considerations (PEDMS 3.1)** in the Pediatric Musculoskeletal Imaging Guidelines depending on the individual's age at the time the mass is discovered. Plain x-ray or ultrasound is not required prior to advanced imaging in these individuals.
• New bone mass(es)	• See: **Bone Tumors - General Considerations (PEDONC-9.1)**
• Documented optic pathway gliomas	• See: **Intracranial Low Grade Gliomas (PEDONC-4.2)**
• Known plexiform neurofibromas	• MRI without and with contrast of a known body area containing a neurofibroma is indicated for any of the following: ◦ Every 3 months for treatment response in individuals receiving active treatment ◦ New or worsening clinical symptoms suggesting progression ◦ Preoperative planning
• Biopsy-proven MPNST in individuals with known NF-1 or NF-2	• For adult individuals, see: **ONC-12 Sarcomas-bone, soft tissue and GIST** • For pediatric individuals, see: **Non-Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS) (PEDONC-8.3)**

Background and Supporting Information

NF1:

- Common syndrome inherited in an autosomal dominant manner (50% risk to offspring) affecting 1 in 2500 people. The diagnosis is commonly made based on

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

established clinical criteria including café-au-lait spots, Lisch nodules of the iris, axillary freckling, family history, and the presence of NF-associated tumors.
- Genetic testing is encouraged for children with possible NF1 and no family history prior to assigning a diagnosis, but will not identify a mutation for all individuals with NF1.
- The majority of tumors are benign in nature, but malignant degeneration can occur.
- NF1-affected persons have increased sensitivity to ionizing radiation, so CT and nuclear medicine imaging are not appropriate screening or surveillance studies for these individuals.
- CT and/or nuclear medicine studies may be indicated for acute clinical situations and should be judged on a case-by-case basis.
- Annual ophthalmology evaluation is strongly recommended beginning at the time of diagnosis of NF1 to evaluate for optic pathway abnormalities:
  - Screening MRIs Brain (CPT® 70553) and Orbits (CPT® 70543) for asymptomatic individuals are **not** generally recommended due to the ~60% rate of unidentified bright objects (UBOs, T2-weighted signal abnormalities) which mostly disappear by age 30
    - Routine follow up imaging of UBOs is not warranted in the absence of acute symptoms suggesting new or worsening intracranial disease
- Individuals with NF1 are at increased risk for plexiform neurofibromas (PN) and malignant peripheral nerve sheath tumors (MPNST— a high grade sarcoma)
  - Screening imaging of asymptomatic individuals for these tumors is not supported by evidence. PET imaging is not supported for PN surveillance in asymptomatic individuals at this time as the positive predictive value is only 60% to 65% even in symptomatic individuals.
- Although PET imaging has a positive predictive value of only 61% to 63% in NF1 with suspected transformation to MPNST, the negative predictive value is high (96% to 99%)
  - Considerations for PET/CT coding and indications/coding for PET/MRI are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**
  - Inconclusive PET findings should lead to biopsy of the concerning lesion.
  - Repeat PET studies are not indicated due to the poor positive predictive value in this setting.
- 2017 AACR recommendations support a single baseline Whole-Body MRI to assess tumor burden in late adolescence or young adulthood. Further imaging should be based on focused MRI for symptomatic changes or pre-operative planning, and further surveillance WBMRI are not supported.

The following imaging studies should be considered medically necessary in individuals with NF2:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• All individuals, beginning at age 10 years	• Annual MRI Brain without and with contrast (CPT® 70553)
• All individuals without a history of spinal tumors, beginning at age 10 years	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 3 years
• All individuals with a history of spinal tumors	• Annual MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
• Clinical symptoms of intracranial mass or vestibular disease	• MRI Brain without and with contrast (CPT® 70553)
• Any of the following: ◦ Clinical symptoms suggestive of new or progressive spinal or paraspinal tumors, including uncomplicated back pain or radiculopathy ◦ Recent diagnosis with a meningioma or vestibular schwannoma	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
• Surveillance for progression of unresected tumors in individuals with known vestibular schwannoma	• Annual MRI Brain without and with contrast (CPT® 70553)
• Known vestibular schwannomas and any of the following: ◦ New or worsening clinical symptoms including hearing loss ◦ Preoperative planning	• MRI Brain without and with contrast (CPT® 70553)
• Known meningioma	• See: **Meningiomas (ONC-2.8)** in the Oncology Imaging Guidelines
• Known ependymoma	• See: **Ependymal Tumors (Ependymoma) (PEDONC-4.8)**

Background and Supporting Information

NF2:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- NF2 is substantially less common than NF1. It is inherited in an autosomal dominant manner (50% risk to offspring) affecting ~1 in 25000 people. NF2 is associated with increased risk for meningiomas (50% of affected individuals), vestibular schwannomas, and spinal tumors (75% of affected individuals).

Beckwith-Wiedemann Syndrome (BWS) (PEDONC-2.4)

ONCP.SC.0002.4.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with BWS:

Indication	Medically Necessary Imaging Study
• All individuals, from birth to the 8th birthday	• Abdominal ultrasound (CPT® 76700) every 3 months
• Purely cystic adrenal mass found on screening ultrasound	• Continue screening ultrasound (CPT® 76700 or 76705) every 3 months without additional imaging (i.e., advanced imaging is not medically necessary for a purely cystic adrenal mass)
• Solid or mixed adrenal mass found on screening ultrasound AND: ◦ Individual age 0 months to 5 months, and ◦ Mass 0 cm to 3 cm in diameter	• MIBG imaging (See: **PEDONC-1.3** for coding) and either CT or MRI Abdomen (contrast as requested)
• Solid or mixed adrenal mass found on screening ultrasound AND: ◦ Individual age 0 to 5 months, and ◦ Mass >3 cm in diameter	• MIBG imaging (See: **PEDONC-1.3** for coding) and MRI Abdomen (contrast as requested)
• Solid or mixed adrenal masses on screening ultrasound AND: ◦ Individual age 6 months or greater	• MIBG imaging (See: **PEDONC-1.3** for coding) prior to biopsy or resection ◦ If no evidence of malignancy on biopsy or resection, resume screening abdominal ultrasound every 3 months
• Solid or mixed adrenal masses on screening ultrasound AND: ◦ No evidence of malignancy based on MIBG, CT or MRI, Urine HVA/ VMA, and serum ACTH	• Repeat abdominal ultrasound (CPT® 76700 or 76705) every 6 weeks for 2 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• Known renal tumors	• See: **Pediatric Renal Tumors (PEDONC-7)**
• Known hepatoblastoma	• See: **Hepatoblastoma (PEDONC-11.2)**
• Known neuroblastoma	• See: **Neuroblastoma (PEDONC-6)**
• Known adrenocortical carcinoma	• See: **Pediatric Adrenocortical Carcinoma (PEDONC-14)**
• Known pheochromocytoma	• See: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)** in the Oncology Imaging Guidelines

Background and Supporting Information

- Inherited syndrome characterized by macroglossia, hemihypertrophy, macrosomia, organomegaly, and neonatal hypoglycemia. Individuals with isolated hemihypertrophy are also imaged according to this guideline.
- Caused by mutation at chromosome 11p15, affected children are predisposed to Wilms tumor, hepatoblastoma, rhabdomyosarcoma, and adrenal tumors.

Proprietary Information of UnitedHealthcare.

Denys-Drash Syndrome (DDS) (PEDONC-2.5)

ONCP.SC.0002.5.A
v2.0.2026

The following imaging studies should be considered appropriate in individuals with DDS:

Indication	Medically Necessary Imaging Study
• All individuals, from birth to the 8th birthday	• Abdominal ultrasound (CPT® 76700) every 3 months
• Known renal tumors	• See: **Pediatric Renal Tumors (PEDONC-7)**

Background and Supporting Information

- Characterized by pseudohermaphroditism, early renal failure, and >90% risk of Wilms tumor development in each kidney. Associated with mutations at 11p13, risk of renal failure after detection of symptomatic Wilms tumor is 62%, so early detection may allow for renal-sparing surgical approaches.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Wilms Tumor-Aniridia-Growth Retardation (WAGR) (PEDONC-2.6)

ONCP.SC.0002.6.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with WAGR:

Indication	Medically Necessary Imaging Study
• All individuals, from birth to the 8th birthday	• Abdominal ultrasound (CPT® 76700) every 3 months
• Known renal tumors	• See: **Pediatric Renal Tumors (PEDONC-7)**

Background and Supporting Information

- Named for the components of the disorder, it is associated with mutations at 11p13. As the name suggests, individuals are predisposed to Wilms tumor, with 57% of individuals in one cohort developing Wilms tumor. Risk of renal failure after detection of symptomatic Wilms tumor is 38%, so early detection may allow for renal-sparing surgical approaches.

Familial Adenomatous Polyposis (FAP) and Related Conditions (PEDONC-2.7)

- Individuals with Lynch, Gardner, and Turcot syndromes should also be imaged according to these guidelines.

The following imaging studies should be considered medically necessary in individuals with FAP and related conditions:

- For colonoscopy and endoscopy guidance for those with FAP and related conditions, See: *EGD-1.16*, *CAPEND-5*, or *COLON-17: Genetic Syndromes* for the endoscopic management of polyposis syndromes.

Indication	Medically Necessary Imaging Study
• All individuals, from birth to the 6th birthday	• Abdominal ultrasound (CPT® 76700) every 3 months
• All individuals, beginning at age 12 years	• Annual thyroid ultrasound (CPT® 76536)
• All individuals, beginning at age 30 years	• Annual pelvic ultrasound (CPT® 76856)
• Family history of desmoid tumors	• Abdominal ultrasound (CPT® 76700) annually for life after age 6
• Individuals with Spigelman Stage III or IV or if duodenectomy is being planned • See: *Genetic Syndromes (EGD-1.16)* for additional information regarding Spigelman staging.	• MR Enterography (MRI Abdomen without and with contrast, CPT® 74183 and MRI Pelvis without and with contrast, CPT® 72197)
• Known colorectal tumors	• See: **Colorectal Cancer (ONC-16)** in the Oncology Imaging Guidelines
• Known desmoid tumors	• See: **Sarcomas – Bone, Soft Tissue, and GIST (ONC-12)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- Inherited in an autosomal dominant manner (50% risk to offspring), it is also known as Adenomatous Polyposis Coli (APC). It is associated with the development of thousands of colonic polyps by age 20 and >90% risk of colorectal carcinoma. Prophylactic total colectomy is recommended by age 20 for most individuals. FAP is also associated with hepatoblastoma, tumors of the pancreas and small bowel, medulloblastoma, and thyroid cancer.

Proprietary Information of UnitedHealthcare.

Multiple Endocrine Neoplasias (MEN) (PEDONC-2.8)

ONCP.SC.0002.8.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with MEN1:

Indication	Medically Necessary Imaging Study
All individuals, beginning at age 5 years	• Annual MRI Brain without and with contrast (CPT® 70553) • Annual MRI Abdomen without and with contrast (CPT® 74183), CT Abdomen with contrast (CPT® 74160), or ultrasound (CPT® 76700) • Annual Octreotide study (see: **PEDONC-1.3** for coding)
All individuals, beginning at age 15 years	• Annual MRI Chest without and with contrast (CPT® 71552) or CT Chest with contrast (CPT® 71260)
Known thyroid cancer	• See: **Thyroid Cancer (ONC-6)** in the Oncology Imaging Guidelines
Known pheochromocytoma	• See: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)** in the Oncology Imaging Guidelines

The following imaging studies should be considered medically necessary in individuals with MEN2a and MEN2b:

Indication	Medically Necessary Imaging Study
All individuals, beginning at age 5 years	• MRI Abdomen without and with contrast (CPT® 74183) every 3 years
• One of the following: ◦ Elevated catecholamines ◦ Inconclusive adrenal mass on MRI	• ONE of the following: ◦ Octreotide study (see: **PEDONC-1.3** for coding) ◦ Adrenal Nuclear Imaging (CPT® 78075)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• Known pheochromocytoma	• See: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)**

Background and Supporting Information

- Inherited in an autosomal dominant manner (50% risk to offspring)
- MEN1 is characterized by parathyroid, pancreatic islet cell, and pituitary gland tumors (3 P's), as well as carcinoid tumors in the chest and abdomen, and 28% of individuals will develop at least one tumor by age 15.
- MEN2a is characterized by medullary thyroid carcinoma, parathyroid adenomas, and pheochromocytomas.
- MEN2b is characterized by ganglioneuromas of the GI tract and skeletal abnormalities presenting in infancy.
- Recommended cancer screening includes:
  - Individuals with MEN2a and MEN2b receive annual measurement of catecholamines for pheochromocytoma screening

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Tuberous Sclerosis Complex (TSC) (PEDONC-2.9)

- Abdominal MRI (CPT® 74183) is medically necessary for women of childbearing age planning pregnancy.

The following imaging studies should be considered medically necessary in individuals with TSC:

Indication	Medically Necessary Imaging Study
• All individuals, at the time of suspected diagnosis until age 25 years	• Annual Brain MRI without and with contrast (CPT® 70553)
• All individuals at diagnosis	• Single baseline MRI Abdomen without and with contrast (CPT® 74183)
• If no renal lesions seen on baseline MRI Abdomen	• From diagnosis through age 11: ◦ Annual Renal US (CPT® 76770) • Age 12 (or 10 years earlier than the youngest family member with renal cell carcinoma, whichever comes earlier): ◦ MRI Abdomen without and with contrast (CPT® 74183) annually in lieu of ultrasound
• For documented renal lesions on baseline MRI Abdomen or any ultrasound	• MRI Abdomen without and with contrast (CPT® 74183) annually
• All individuals, beginning at age 18 years	• CT Chest without contrast (CPT® 71250) every 5 years
• All individuals, for cardiac screening or follow up of known cardiac disease	• See: **Initial Transthoracic Echocardiography (TTE) Indications (PEDCD-8.2)** and **Repeat Transthoracic Echocardiography Indications (PEDCD-8.3)** in the Pediatric Cardiology Imaging Guidelines
• Individuals with documented abnormalities on baseline CT Chest	• Additional CT Chest without contrast or with contrast (CPT® 71250 or 71260) every 1 year

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
• Any of the following: ◦ New pulmonary symptoms ◦ Worsening pulmonary function testing	• CT Chest without contrast (CPT® 71250)
• Known SEGA tumors	• See: **Intracranial Low Grade Gliomas (LGG) (PEDONC-4.2)**
• Known renal cell carcinoma	• See: **Pediatric Renal Cell Carcinoma (RCC) (PEDONC-7.4)**

Background and Supporting Information

- Inherited in an autosomal dominant manner (50% risk to offspring), affecting ~1 in 6000 individuals, it is associated with benign tumors, hypopigmented skin macules (ash leaf spots), developmental delay, and epilepsy.
- Malignancies associated with this syndrome include:
  - Subependymal giant cell astrocytomas (SEGA tumors)
    - Historically, early surgery was important to reduce morbidity related to these tumors
    - More recently, everolimus has been successfully used to treat these tumors without surgery, and early detection remains an important feature for success
  - Renal cell carcinoma
  - Cardiac rhabdomyosarcoma
  - Pulmonary lymphangioleiomyomatosis
- Recommended cancer screening includes:
  - Ophthalmologic and dermatologic evaluation annually

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Von Hippel-Lindau Syndrome (VHL) (PEDONC-2.10)

ONCP.SC.0002.10.A
v2.0.2026

The following imaging studies are considered medically necessary in individuals with VHL:

Indication	Medically Necessary Imaging Study
• All individuals, beginning at age 11 years	• MRI Brain without and with contrast (CPT® 70553) and MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, and Lumbar-CPT® 72158) every 2 years
• Individuals with frequent ear infections, prior to age 8	• One-time MRI Brain without and with contrast (CPT® 70553)
• All individuals, beginning at age 5 years	• Annual Abdominal US (CPT® 76700)
• All individuals, beginning at age 15 years	• MRI Abdomen without and with contrast (CPT® 74183) every 2 years
• Suspected pheochromocytoma as indicated by **ONE** of the following: ◦ Elevated catecholamines ◦ Inconclusive adrenal mass on MRI	• Octreotide study (CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, or CPT® 78804) or Adrenal Nuclear imaging study or Adrenal Nuclear imaging (CPT® 78075) or Dotatate PET (CPT® 78815 or CPT® 78816)
• Individuals with known hemangioblastoma anywhere in the body (based on imaging) that has not been resected	• Both of the following, every 1 year: ◦ MRI Brain without and with contrast (CPT® 70553) ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, and Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
• Known hemangioblastoma that has not been resected and new or worsening symptoms	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, and Lumbar-CPT® 72158)
• Known (based on imaging) CNS hemangioblastoma	• See: **Intracranial Low Grade Gliomas (LGG) (PEDONC-4.2)**
• Known renal cell carcinoma	• See: **Pediatric Renal Cell Carcinoma (RCC) (PEDONC-7.4)**
• Known pheochromocytoma or other neuroendocrine tumor	• See: **Neuroendocrine Cancers And Adrenal Tumors (ONC-15)** in the Oncology Imaging Guidelines
• New abnormality is detected on MRI brain	• A repeat MRI Brain without and with contrast (CPT® 70553) should be done in 6 months. • If stable, imaging should return to every 2 years starting 2 years from the prior study
• New abnormality is found in the pancreas on a screening MRI abdomen	• Repeat MRI Abdomen without and with contrast (CPT® 74183) in 6 months then annually from initial scan to observe for development of pNET

Background and Supporting Information

- Inherited in an autosomal dominant manner (50% risk to offspring), it is associated with CNS hemangioblastomas, retinal angiomas, endolymphatic sac tumors (ELST), gastrointestinal stromal tumor (GIST), renal cell carcinoma (RCC), and pheochromocytomas and other neuroendocrine tumors (NETs). Pediatric individuals are at risk of developing hemangioblastomas and pheochromocytomas that can remain clinically occult until symptoms become severe. Historically, substantial mortality was attributable to RCC, pancreatic NET, and CNS hemangioblastoma.
- Recommended cancer screening includes:
  - Annual ophthalmologic evaluation beginning at birth
  - Annual measurement of catecholamines beginning at age 2
  - Audiology assessment every 2 years beginning at age 5

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Rhabdoid Tumor Predisposition Syndrome (PEDONC-2.11)

ONCP.SC.0002.11.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with Rhabdoid Tumor Predisposition Syndrome:

Indication	Medically Necessary Imaging Study
• All individuals, at diagnosis, as early as birth if requested	• Whole-body MRI (WBMRI) (CPT® 76498)
• All individuals, from birth to 6 months of age	• ALL of the following, monthly: ◦ US Head (CPT® 76506) ◦ US Abdomen (CPT® 76700) ◦ US Pelvis (CPT® 76856) ◦ US Neck (CPT® 76536) ◦ MRI with and without contrast of areas of concern found on baseline WBMRI
• All individuals, from age 7 months to 5 years	• ALL of the following, every 3 months: ◦ US Abdomen (CPT® 76700) ◦ US Pelvis (CPT® 76856) ◦ US Neck (CPT® 76536) ◦ MRI Brain (CPT® 70553) ◦ MRI Spine (CPT® 72156, CPT® 72157, and CPT® 72158) without and with contrast ◦ MRI with and without contrast of areas of concern found on baseline WBMRI
• All individuals, after age 5 years	• Annual WBMRI (CPT® 76498)
• Clinical symptoms or WBMRI findings suggesting malignancy	• Targeted advanced imaging of the suspected disease site (CT with or without contrast, or MRI without and with contrast)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• Inconclusive findings on ultrasound	• MRI with and without contrast of the inconclusive US site ◦ MRI is then medically necessary in place of ultrasound for remainder of planned screening

Background and Supporting Information

- Inherited in an autosomal dominant manner (50% risk to offspring), it is associated with malignant rhabdoid tumors of the kidney and extrarenal locations, and atypical teratoid/rhabdoid tumors (ATRT) of the CNS. It is caused by a germline mutation in *INI1* or *SMARCB1*, and is associated with a more variable prognosis than de novo rhabdoid tumors.

Click Here to Return to the Main TOC

Familial Retinoblastoma Syndrome (PEDONC-2.12)

- Regular physical and ophthalmologic evaluations under anesthesia (EUA) are the hallmark of surveillance strategies for these individuals, and asymptomatic screening imaging does not have a defined role at this time.

The following imaging studies should be considered medically necessary in individuals with Familial Retinoblastoma Syndrome:

Indication	Medically Necessary Imaging Study
• Individuals with retinomas (premalignant retinal lesions)	• Annual MRI Orbits (CPT® 70543)
• Either of the following: ◦ Inconclusive EUA findings ◦ New symptoms	• US Orbits (CPT® 76512, 76510, or 76511) or MRI Orbits (CPT® 70543) ◦ These studies should be used if at all possible in lieu of CT or nuclear imaging to avoid radiation exposure

Background and Supporting Information

- This syndrome is inherited in an autosomal dominant manner (50% risk to offspring). As the name suggests, it is associated with retinoblastoma, as well as osteosarcoma, pediatric melanoma, and a significantly increased risk for radiation-related malignancies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Hereditary Paraganglioma-Pheochromocytoma (HPP) Syndromes (PEDONC-2.13)

ONCP.SC.0002.13.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with HPP Syndromes:

Indication	Medically Necessary Imaging Study
• All individuals with SDHx (SDHA, SDHB, SDHC, SDHD), MAX, TMEM127 mutations, beginning at age 6	• Every 2 years, ONE of the following sets of imaging: ◦ Whole-body MRI (CPT® 76498) ▪ CPT® 76498 is the only code for whole-body MRI at this time OR ◦ MRI Neck without and with contrast (CPT® 70543), MRI Chest without and with contrast (CPT® 71552), MRI Abdomen without and with contrast (CPT® 74183), and MRI Pelvis without and with contrast (CPT® 72197) ▪ If MRI cannot be performed: CT Neck with contrast (CPT® 70491), CT Chest with contrast (CPT® 71260), and CT Abdomen and Pelvis with contrast (CPT® 74177) ▪ MRI Neck imaging should include skull base, thus separate MRI Brain (CPT® 70553) is only medically necessary if there are CNS-specific symptoms.
• Initial screening for individuals diagnosed at age 18 or older	• One-time PET/CT (CPT® 78815 or 78816), with 68Ga-DOTA-SSAs ◦ FDG may be substituted if Dotatate radiotracers are not available
• Known pheochromocytoma or other neuroendocrine tumors	• See: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)** in the Oncology Imaging Guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- Caused by mutations in *SDHx* and related genes, this syndrome is inherited in an autosomal dominant manner (50% risk to offspring), and is associated with pheochromocytomas and paragangliomas.
- Individuals with multiple endocrine neoplasias should not use this guideline and should be imaged according to **Multiple Endocrine Neoplasias (MEN) (PEDONC-2.8)**.
- MRI is preferred to CT to minimize radiation exposure given these individuals' lifelong need for screening
- All individuals with HPP receive annual measurement of catecholamines
- EANM–SNMMI joint guidelines propose the use of 68Ga-DOTA-SSAs PET as the first-choice functional imaging modality in adult SDHx mutation carriers and the use of 18F-FDG when 68Ga-DOTA-SSAs PET is not available.

Costello Syndrome (PEDONC-2.14)

ONCP.SC.0002.14.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with Costello Syndrome:

Indication	Medically Necessary Imaging Study
• Following confirmation of gene mutation	• ANY or ALL of the following: ◦ Echocardiogram ▪ CPT® 93306 or ▪ CPT® 93308 with 93321 and 93325 ◦ MRI Brain (CPT® 70553) without and with contrast ◦ MRI Cervical (CPT® 72156) and Thoracic Spine (CPT® 72157) without and with contrast
• All individuals, from birth to 10th birthday	• Every 3 months: ◦ US Abdomen (CPT® 76700) and Pelvis (CPT® 76856)
• Known cardiac disease	• See: **Initial Transthoracic Echocardiography (TTE) Indications (PEDCD-8.2)** and **Repeat Transthoracic Echocardiography Indications (PEDCD-8.3)** in the Pediatric Cardiology Guidelines
• Known rhabdomyosarcoma	• See: **Rhabdomyosarcoma (RMS) (PEDONC-8.2)**
• Known neuroblastoma	• See: **Neuroblastoma (PEDONC-6)**

Background and Supporting Information

- Caused by mutations in *HRAS* genes, this syndrome is inherited in an autosomal dominant manner (50% risk to offspring), and is associated with rhabdomyosarcoma and neuroblastoma in early childhood, and transitional cell cancer of the bladder in older children and adults.

Constitutional Mismatch Repair Deficiency (CMMRD or Turcot Syndrome) (PEDONC-2.15)

ONCP.SC.0002.15.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with CMMRD/Turcot Syndrome:

Indication	Medically Necessary Imaging Study
• All individuals, after CMMRD diagnosis is confirmed by genetic mutation	• MRI Brain without and with contrast (CPT® 70553) every 6 months
• All individuals, beginning at age 4 years	• Annual esophagogastroduodenoscopy and colonoscopy
• All individuals, beginning at age 6 years	• Annual whole-body MRI (CPT® 76498) ◦ 76498 is the only code for whole-body MRI at this time

Background and Supporting Information

- A highly penetrant and aggressive cancer predisposing syndrome resulting from autosomal recessive inheritance of biallelic mutations in mismatch repair genes, CMMRD syndrome leads to substantial risk for several commonly fatal childhood malignancies - high-grade CNS tumors (glioma, PNET, medulloblastoma) and hematologic malignancies (non-Hodgkin lymphoma, acute lymphoblastic leukemia). Individuals with CMMRD are also at increased risk for gastrointestinal tumors.

Hereditary Leiomyomatosis and Renal Cell Cancer (HLRCC) (PEDONC-2.16)

ONCP.SC.0002.16.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with HLRCC:

Indication	Medically Necessary Imaging Study
• Beginning at age 8 years, individuals with at least ONE of the following: ◦ Documented fumarate hydratase (FH) gene mutation/variant consistent with HLRCC ◦ Histologically confirmed multiple cutaneous piloleiomyomas ◦ At least TWO of the following manifestations: ▪ Surgical treatment for symptomatic uterine leiomyomas before age 40 ▪ Type 2 papillary renal cell carcinoma or collecting duct renal carcinoma before age 40 ▪ A first-degree family member with either of the two above criteria	• MRI Abdomen with and without contrast (CPT® 74183), annually

Background and Supporting Information

- Hereditary leiomyomatosis and renal cell cancer (HLRCC) is a disorder in which affected individuals tend to develop benign tumors containing smooth muscle tissue (leiomyomas) in the skin and, in females, the uterus. Approximately 20 percent of people with HLRCC develop renal cell cancer. People with HLRCC are commonly diagnosed with kidney cancer in their forties but cases have been reported in individuals as young as 11.
- In 2019, Forde et. al. published the first large, prospective study of screening for HLRCC and showed that most symptomatic individuals present with stage 3 or 4 RCC with a high risk of death and one life is saved for every 5 individuals on an MRI screening protocol.

Other Renal Cell Cancer Predisposition Syndromes (PEDONC-2.17)

ONCP.SC.0002.17.A
v2.0.2026

Birt-Hogg-Dube Syndrome (BHDS)

The following imaging studies should be considered medically necessary in individuals with BHDS:

Indication	Medically Necessary Imaging Study
• All individuals, beginning at age 20 years	• MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) annually ◦ If no family history of renal tumors AND after 2 consecutive normal MRIs, MRI is medically necessary every 2 years

Background and Supporting Information

- Birt-Hogg-Dube Syndrome (BHDS) in an autosomal dominant disorder with a heterozygous pathogenic variant in FLCN gene.
- These individuals have, or may have:
  - Cutaneous manifestations (fibrofolliculomas, acrochordons, angiofibromas, oral papules, cutaneous collagenomas, and epidermal cysts)
  - Pulmonary cysts/history of pneumothorax
  - A seven-fold increase in renal tumors
    - The most common renal tumors are oncocytoma, chromophobe, and a hybrid of these two.
    - Renal tumors may be multifocal and bilateral.
    - Median age of renal tumor diagnosis is 48 years.
- Recommended cancer screening includes:
  - Screening colonoscopy starting at age 40
    - Earlier colonoscopy may be considered for those with a family history of colorectal cancer earlier than age 40.

BAP1 Tumor Predisposition Syndrome

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

The following imaging studies should be considered medically necessary in individuals with BAP1:

Indication	Medically Necessary Imaging Study
• All individuals, beginning at age 30 years	• Abdominal MRI with and without contrast (CPT® 74183) every 2 years

Background and Supporting Information

BAP1 tumor predisposition syndrome (TPDS) is an autosomal dominant condition with a predisposition to melanoma (ocular and cutaneous), mesothelioma, clear cell renal cancer, and chromophobe renal cancer.

Hereditary Papillary Renal Carcinoma (HPRC)

The following imaging studies should be considered medically necessary in individuals with HPRC:

Indication	Medically Necessary Imaging Study
• All individuals, beginning at age 30 years	• Abdominal MRI with and without contrast (CPT® 74183) annually

Background and Supporting Information

- Hereditary papillary renal carcinoma (HPRC) is an autosomal dominant condition involving the MET gene and predisposes individuals to multifocal, bilateral renal tumors.

DICER1

The following imaging studies should be considered medically necessary in individuals with DICER1:

Indication	Medically Necessary Imaging Study
• DICER1 mutation asymptomatic lung surveillance	• Once at age 3-6 months of age and again at 2.5-3 years of age: ◦ CT Chest (contrast as requested) • In addition, chest x-ray at birth and every 6 months until 8 years of age and annually until age 12

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• DICER1 mutation asymptomatic abdominal and pelvic surveillance	• Every 3 months, from birth to the 8th birthday, then every 12 months until 12 years of age: ◦ Abdominal US (CPT® 76700) • After age 12, it is medically necessary for females with DICER1 mutation to continue abdominal and pelvic ultrasounds (CPT® 76700 and CPT® 76856 or CPT® 76857) annually until age 40
• DICER1 mutation thyroid surveillance	• Baseline thyroid US (CPT® 76536) by 8 years of age then every 3 years
• Individuals with DICER1 mutation and new CNS symptoms	• MRI Brain without and with contrast (CPT® 70553)

Other Renal Predisposition Syndromes

The following imaging studies should be considered medically necessary in individuals with other renal predisposition syndromes:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• Individuals with any of the following genetic variants or syndromes: ◦ REST, TRIM28, FBXW7, NYNRIN, KDM3B, XPO5, CHECK2, PALB2, CTNNB1, DROSHA, WT1 and 2, WTX, DGCR8, SIC1 and 2, BCORL1, MLLT1, MYCN, DIS3L2 ◦ Bloom Syndrome/BLM mutations ◦ Frasier Syndrome ◦ Trisomy 18 ◦ Perlman Syndrome ◦ Bohring-Opitz Syndrome (ASXL1) ◦ MULIBREY and Nanism Syndrome ◦ Congenital anomalies associated with Wilms Tumor ▪ Horseshoe kidney ▪ Renal ectopia, hypoplasia, or renal/ureteral duplication ▪ Congenital mesoblastic nephroma	• Every 3 months, from birth to the 8th birthday: ◦ Abdominal US (CPT® 76700)

Background and Supporting Information

- The list of syndromes and congenital anomalies associated with Wilms Tumor specifically is ever growing. The following genetic variants and syndromes, not otherwise listed in **PEDONC-2** for more specific imaging, may have imaging as shown above.

Infantile Myofibromatosis (PEDONC-2.18)

ONCP.SC.0002.18.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with Infantile Myofibromatosis:

Indication	Medically Necessary Imaging Study
• Assess for the presence of multifocal disease in children under two years of age	• WBMRI (CPT® 76498) once within 6 months of diagnosis
• Pre-operative planning or • Signs or symptoms suggesting progression that may require treatment with surgery or chemotherapy	• Imaging of cutaneous/muscular sites with MRI with and without contrast of symptomatic sites or sites requiring treatment.
• Unresected, known visceral sites of disease	• MRI with and without contrast of unresected visceral involved sites, every 6 months until the age of two years
• Post-operative evaluation and both of the following: ◦ Adequacy of resection is unclear and ◦ Re-excision is being considered	• One-time MRI with and without contrast
• Surveillance for emergence of visceral disease	• Every 6 months, until the age of two years: ◦ CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Abdomen and Pelvis (CPT® 74177) • CT should not duplicate simultaneous MRI imaging of involved sites
• Individuals requiring chemotherapy	• See: **PEDONC-8.3**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- Infantile myofibromatosis is a benign condition characterized by soft tissue tumors, 90% of which present in the first 2 years of life. 75% of cases present as solitary lesions affecting the skin and/or muscles of the head, neck and trunk. Other patterns of inheritance include congenital multicentric disease limited to skin and muscle, congenital multicentric with a single visceral site, and congenital with multiple visceral site involvement.
- The condition is most commonly sporadic, though familial cases associated with *PDGFRB* and *NOTCH3* have been described
- The majority of cases with skin or muscle only involvement regress spontaneously.
- Visceral cases are lethal in the absence of therapy in 75% of cases due to organ compression, particularly with cardiopulmonary involvement.
- If vital structures are involved or significant symptoms occur, treatment is generally radical resection. Chemotherapy is sometimes utilized for progressive or multifocal life threatening lesions.
- Infants may present with a single lesion and develop further lesions in the first two years of life. This scenario, along with the inability of infants to readily express symptoms, impacts the imaging studies that may be approved.
- Routine surveillance of cutaneous/muscular sites is not supported as spontaneous regression is common.
- Surveillance beyond the age of two years is not supported.

Bloom Syndrome (PEDONC-2.19)

ONCP.SC.0002.19.A
v2.0.2026

The following imaging studies should be considered medically necessary in individuals with Bloom Syndrome:

Indication	Medically Necessary Imaging Study
Malignancy screening particularly lymphomas	• Every 2 years, starting at age 13: ◦ Whole-Body MRI (CPT® 76498)
Wilms tumor screening	• See: **Other Renal Cell Cancer Predisposition Syndromes (PEDONC-2.17)**
Gastrointestinal tumor screening	• There is no strong data to support endoscopic screening
Breast cancer screening	• There is no strong data to support Breast MRI. See: **Breast MRI Indications (BR-5.1)** for any updates to imaging

Click Here to Return to the Main TOC

Pediatric Leukemia General Considerations (PEDONC-3.1)

- MRI Brain without and with contrast (CPT® 70553) is medically necessary in individuals exhibiting CNS symptoms
  - CT Head without or with contrast (CPT® 70450 or CPT® 70460) is medically necessary for urgent concerns where MRI would delay care (i.e., suspected CNS bleeding)
  - Imaging due to CSF tumor burden has not been shown to improve the detection of CNS involvement compared with CSF alone
- See: **Hematopoietic Stem Cell Transplantation (ONC-29)** for imaging guidelines related to transplant

Background and Supporting Information

- The overwhelming majority of leukemias occurring in children are acute. Chronic myelogenous leukemia (CML) is rare in children, and the occurrence of chronic lymphocytic leukemia (CLL) appears to have only been reported once in pediatric individuals to date
- Routine advanced imaging is not indicated in the evaluation and management of chronic myeloid leukemia in the absence of specific localizing clinical symptoms or clearance for hematopoietic stem cell transplantation

Click Here to Return to the Main TOC

Acute Lymphoblastic Leukemia (ALL) (PEDONC-3.2)

ONCP.LE.0003.2.A
v2.0.2026

- Individuals with B-precursor or T-cell lymphoblastic lymphoma without bone marrow involvement are treated similarly to individuals with leukemia of the same cell type and should be imaged according to this guideline section
- This section does not apply to individuals with mature B-cell histology (primarily Burkitt's in children). Please refer to **Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL) (PEDONC-5.3)** for guidelines for these individuals
- Scrotal Ultrasound CPT® 76870 and/or doppler ultrasound of the scrotum CPT® 93975 or 93976 is medically necessary for suspected testicular involvement.
- Chest x-ray should be performed to evaluate for mediastinal mass in suspected cases or upon initial diagnosis.
  - CT Chest with contrast (CPT® 71260) is medically necessary to immediately evaluate for airway compression and anesthesia safety prior to attempting histologic diagnosis if mediastinal widening is seen on chest x-ray
  - In individuals with known or strongly suspected T-cell histology or other suspected lymphoblastic lymphoma involvement, EITHER of the following is medically necessary for initial staging purposes:
    - CT Neck (CPT® 70491), CT Chest (CPT® 71260), and CT Abdomen and Pelvis (CPT® 74177) with contrast OR
    - PET/CT (CPT® 78816)
    - Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**
- MRI Brain without and with contrast (CPT® 70553) is medically necessary for individuals exhibiting CNS symptoms.
  - Imaging due to CSF tumor burden has not been shown to improve the detection of CNS involvement compared with CSF alone.
    - CT Head without or with contrast (CPT® 70450 or CPT® 70460) is medically necessary for urgent concerns where MRI would delay care (i.e., suspected CNS bleeding)

Additional imaging in lymphoblastic lymphoma/lymphomatous extramedullary disease:

- CT is medically necessary to assess response to therapy **only** for individuals with known bulky nodal disease (usually with T-cell histology) at the end of induction (4

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

to 6 weeks). CT is medically necessary for individuals with residual masses every new therapy phase (Consolidation, Interim maintenance, etc., generally every 8 to 12 weeks) until disease resolution is seen
- PET/CT (CPT® 78815) is medically necessary when residual mass ≥8 mm in diameter is present on recent CT imaging **and** immediate radiation or chemotherapy plan will be based on results.
  - Residual mass of any size with no PET-avidity is considered a complete response at the extranodal/lymphomatous site.
- Chest x-ray or Abdominal ultrasound (CPT® 76700) **only**, as indicated by site(s) of bulky disease present at diagnosis, is medically necessary for further surveillance, once CT imaging shows no evidence of disease.
- CT of all involved bulky nodal areas is medically necessary in individuals with persistent residual masses performed as part of an end of therapy evaluation

Immunosuppression during ALL therapy:

- CT or MRI is medically necessary for infectious disease concerns for individuals with ALL with:
  - Absolute neutrophil count (ANC) <500 or
  - Inconclusive findings on chest x-ray **or** ultrasound at any ANC during active treatment
- Individuals with ALL are severely immunocompromised during the first 4 to 6 weeks of treatment (induction) and any conventional imaging request to evaluate for infectious complications during this time frame is medically necessary
- MRA/MRV of the head (CPT® 70544, 70545, or 70546) is medically necessary for the following:
  - To rule out bleeding associated with sinus venous thrombosis in individuals treated with asparaginase

Imaging during therapy for relapsed ALL:

- Frequent CT or MRI imaging is medically necessary to evaluate known or suspected new sites of invasive fungal or other aggressive infections
- Surveillance imaging of asymptomatic individuals to detect invasive fungal infection is medically necessary **only** when acute clinical decisions will be made based on the imaging

Imaging of known or suspected osteonecrosis in ALL:

- MRI without contrast or without and with contrast of the affected joint(s) is medically necessary for symptoms suggesting osteonecrosis
  - CT without contrast is medically necessary when MRI is contraindicated or unavailable, or for diagnosis of suspected subchondral fracture

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI Bilateral Hips (CPT® 73721 or CPT® 73723 with modifier -50) is medically necessary once at 6 to 9 months after diagnosis for individuals age ≥11 years
- Repeat MRI without contrast of the affected joint(s) is medically necessary every 2 cycles of maintenance (every 6 months) if reintroduction of corticosteroids is being considered in individuals whose symptoms have resolved and are still receiving active treatment
- MRI without contrast of the affected joint(s) is medically necessary for preoperative planning for individuals undergoing core decompression
- See: **Osteonecrosis In Long Term Cancer Survivors (PEDONC-19.4)** for information on osteonecrosis in ALL individuals who have completed therapy

Background and Supporting Information

- The majority of individuals with ALL have B-precursor ALL and routine advanced imaging is not necessary.
- Individuals with ALL who relapse are treated with very intensive chemotherapy regimens and most spend the majority of their chemotherapy treatment phase in the hospital
- Individuals may have therapy-induced hypogammaglobulinemia which requires supplemental intravenous immune globulin (IVIG) during maintenance therapy. Those receiving supplemental IVIG should be treated similarly to individuals with ANC <500 with regards to imaging for infectious disease
- Osteonecrosis (ON) in individuals with ALL is a relatively common complication of ALL and its treatment, primary corticosteroids. Approximately 3% of younger children and 12 to 15% of adolescents are affected by ON at some point during therapy. The peak incidence occurs approximately one year from the time of diagnosis
- Screening MRI of asymptomatic individuals age ≤10 years to detect osteonecrosis has not been shown to impact individual outcomes, and it is not standard to alter treatment based on imaging findings alone without symptoms
- If osteonecrosis is detected on initial MRI, corticosteroids are often withheld during maintenance chemotherapy (but continued in earlier phases of therapy).

Acute Myeloid Leukemia (AML) (PEDONC-3.3)

ONCP.LE.0003.3.A

v2.0.2026

- Frequent CT or MRI imaging is medically necessary to evaluate known sites of invasive fungal infection
- Surveillance imaging of asymptomatic individuals is medically necessary to detect invasive fungal infection **only** when acute clinical decisions will be made based on the imaging
- Advanced imaging may be approved on a case-by-case basis for rare individuals with bulky tumor masses (commonly referred to as chloromas, leukemic sarcomas, or myeloid sarcomas) noted on physical examination or other imaging such as plain film or ultrasound

Background and Supporting Information

- The majority of AML individuals do not have any bulky disease and routine advanced imaging is not necessary
- AML individuals are treated with very intensive chemotherapy regimens and spend the majority of their chemotherapy treatment phase in the hospital

CNS Tumors (PEDONC-4)

Guideline

CNS Tumors General Considerations (PEDONC-4.1)
CNS Low Grade Gliomas (LGG) (PEDONC-4.2)
CNS High Grade Gliomas (HGG) (PEDONC-4.3)
Medulloblastoma (MDB), Other CNS Embryonal Tumors, and Pineoblastoma (PEDONC-4.4)
Atypical Teratoid/Rhabdoid Tumors (ATRT) (PEDONC-4.5)
Pineocytomas and Pineal Parenchymal Tumors (PEDONC-4.6)
CNS Germinomas and Non-Germinomatous Germ Cell Tumors (NGGCT) (PEDONC-4.7)
Ependymal Tumors (Ependymoma) (PEDONC-4.8)
Malignant Tumors of the Spinal Cord (PEDONC-4.9)
Craniopharyngioma and Other Tumors of the Sellar Region (PEDONC-4.10)
Primary CNS Lymphoma (PEDONC-4.11)
Meningiomas (PEDONC-4.12)
Choroid Plexus Tumors (PEDONC-4.13)
References (PEDONC-4)

CNS Tumors General Considerations (PEDONC-4.1)

ONCP.CT.0004.1.A

v2.0.2026

- The classification of pediatric central nervous tumors has recently been revised to incorporate molecular biomarkers in addition to histology, immunohistochemical results and ultrastructure characteristics. The changes in nomenclature are incorporated in these guidelines.
- Central nervous system tumors are the second most common form of childhood cancer, accounting for ~20% of all pediatric malignancies

Red Flag Symptoms Raising Suspicion for CNS Tumors Include:
Any headache complaint from a child age ≤5 years
Headaches awakening from sleep
Focal findings on neurologic exam
Clumsiness (common description of gait or coordination problems in young children)
Headaches associated with morning nausea/vomiting
New onset of seizure activity with focal features
Papilledema on physical exam
Loss of developmental milestones (infants and young children)

MRI Considerations

- MRI is the preferred imaging modality for all pediatric CNS tumors
  - MRI Brain without and with contrast (CPT® 70553) is the primary imaging study for pediatric brain tumors
  - MRI Brain without contrast (CPT® 70551) if requested for initial evaluation of suspected CNS tumor for children able to undergo MRI without sedation
  - Initial MRI should be performed without and with contrast in order to avoid a second anesthesia exposure in younger children requiring sedation for MRI

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) can be substituted where MRI Spine without and with contrast is indicated, if being performed immediately following a contrast-enhanced MRI Brain
- Functional MRI (fMRI) (CPT® 70555 or CPT® 70554) is medically necessary to depict spatial relationships between eloquent cortex and neoplasms for preoperative planning and to promote safe resections (following baseline MRI Brain).
- Refer to **Neuronavigation (HD-28.2)** for additional guidance on perioperative imaging.
- MRI Orbits without and with contrast (CPT® 70543) is medically necessary in individuals who present with papilledema, altered vision, strabismus, nystagmus, anisocoria, proptosis, ocular cranial nerve palsies, coloboma, or leukocoria.

CT Considerations

- CT for evaluation of ventriculomegaly or other operative considerations, or for children who cannot undergo MRI safely
  - CT for evaluation of headaches related to head trauma or evaluation of skull or facial bone abnormalities
  - Post-contrast CT is generally not indicated
- CT is not a recommended study for evaluation of pediatric headache when brain tumor is clinically suspected because of its limited diagnostic accuracy in this area. MRI should be used as first line imaging in these cases
- CT should not be used in place of MRI to avoid sedation in young children when red flag symptoms for CNS tumors are present

MRA/CTA and Perfusion Studies

- MRA or CTA **only** for preoperative planning or to clarify inconclusive findings on MRI or CT
- CT and MRI Perfusion
  - See: **CT or MRI Perfusion (HD-24.5)** in the Head Imaging guidelines

MR Spectroscopy (MRS, CPT® 76390)

- MRS is **only** medically necessary for use in brain tumors of specified histologies where diagnostic accuracy has been established in peer-reviewed literature
  - See diagnosis-specific guidelines for MRS indications
- MRS is considered not medically necessary for all other histologies and indications not listed in a diagnosis-specific guideline section
- MR spectroscopy is not medically necessary for routine surveillance

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

PET Brain Imaging (CPT® 78608 and CPT® 78609)

- PET Brain Metabolic imaging (CPT® 78608) is **only** medically necessary for use in brain tumors of specified histologies where diagnostic accuracy has been established in peer-reviewed literature
  - See diagnosis-specific guidelines for PET indications
- PET Brain Metabolic is not medically necessary for routine surveillance
- PET Brain Metabolic imaging is considered not medically necessary for all other histologies and indications not listed in a diagnosis-specific guideline section
- PET Brain Perfusion imaging (CPT® 78609) is not medically necessary in the evaluation or management of primary CNS tumors
- Fusion PET/CT studies (CPT® 78814, CPT® 78815, or CPT® 78816) are not medically necessary in the evaluation or management of primary CNS tumors

Timing and Frequency of Imaging

- Definitive imaging should be completed prior to considering biopsy given the high degree of morbidity associated with operating on the CNS
  - Occasionally biopsy is not necessary because the imaging findings provide a definitive diagnosis
    - Examples include diffuse intrinsic pontine glioma and optic pathway gliomas in an individual with known neurofibromatosis
- Perioperative imaging frequency
  - Children may undergo very frequent imaging in the immediate perioperative period around resection or debulking of a CNS tumor due to the small anatomic spaces involved
    - Requests for imaging during this time period to specifically evaluate postoperative course or ventriculoperitoneal shunt functioning are medically necessary
  - MRI Brain without and with contrast (CPT® 70553) is medically necessary one time in the immediate preoperative period (even if another study has already been completed) to gain additional information which can be important in optimizing individual outcomes, such as:
    - Completion of additional specialized MRI sequences such as diffusion-tensor imaging
    - Perfusion imaging (CPT® 70553, 70551, OR 70552)
    - Tractography
    - Other sequences not reported under a separate CPT® code but not part of a routine MRI Brain series
  - Repeat MRI Brain that is being requested solely for loading into operative navigation software should not be requested as a diagnostic code but is medically necessary under a treatment planning code (CPT® 76498).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- **Clinical note**: for all pediatric CNS tumors, cerebrospinal fluid pathology positive for malignancy is considered leptomeningeal/spinal disease.

CNS Low Grade Gliomas (LGG) (PEDONC-4.2)

ONCP.CT.0004.2.A
v2.0.2026

- MR Spectroscopy and PET Brain Metabolic are not medically necessary for routine surveillance.
- MRI is generally superior to CT for staging and restaging CNS malignancies, but CT is medically necessary in accordance with these guidelines where MRI is contraindicated.

Indication	Medically Necessary Imaging Study
Initial staging of all LGG	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • MRI Orbits without and with contrast (CPT® 70543) in addition to the above studies for individuals presenting with visual signs or symptoms as listed in **PEDONC-4.1**
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2).**
• At any time, for ANY of the following: ◦ For rapid assessment in the acute setting ◦ Evaluation of acute intracranial hemorrhage ◦ Evaluation of ventriculomegaly ◦ Evaluation of shunt-related issues	• CT Head without contrast (CPT® 70450)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• ANY of the following: ◦ Determining the need for biopsy when transformation to high grade glioma is suspected based on clinical symptoms or recent MRI findings ◦ Evaluation of a brain lesion of indeterminate nature when the PET findings will be used to determine whether biopsy/resection can be safely postponed	• PET Brain Metabolic imaging (CPT® 78608)
• ANY of the following: ◦ Distinguish low grade from high grade gliomas ◦ Evaluate a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed ◦ Distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy	• MR Spectroscopy (MRS, CPT® 76390)
Baseline imaging after resection, to assess degree of resection	• MRI Brain without and with contrast (CPT® 70553) • MRI with and without contrast at level of resected spinal site • If orbital resection, MRI Orbits without and with contrast (CPT® 70543)
Treatment response at the completion of radiotherapy	• MRI Brain without and with contrast (CPT® 70553) • MRI with and without contrast at level of irradiated spinal site • If prior orbital involvement, MRI Orbits without and with contrast (CPT® 70543)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Treatment response on chemotherapy	• MRI Brain without and with contrast (CPT® 70553) approved every 2 cycles during active treatment and at the end of planned chemotherapy • If prior orbital involvement, MRI Orbits without and with contrast (CPT® 70543)
Additional treatment response imaging during induction chemotherapy for individuals with measurable spinal cord disease on MRI	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycles

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Surveillance, including individuals with unresected disease on observation only	• For individuals with intracranial primary: ◦ MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter. ◦ If prior orbital involvement, MRI Orbits without and with contrast (CPT® 70543) ◦ MRI Spine is not medically necessary during surveillance in individuals without prior history of spinal involvement except to evaluate symptoms suspicious for spinal cord recurrence • For individuals with a history of spine primary tumor or metastatic spinal involvement: ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter • For individuals with NF1 **ANY** of the following: ◦ MRI Brain without and with contrast (CPT® 70553 every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter ◦ MRI Orbits without and with contrast (CPT® 70543) every 3 months for 2 years, then every 6 months for 3 years, then annually thereafter
Suspected intracranial or intraspinal recurrence	• All imaging supported in initial staging criteria

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

Includes the following tumors:
• Pediatric-type diffuse low-grade gliomas ◦ Diffuse astrocytoma, MYB- or MYBL1-altered ◦ Angiocentric glioma ◦ Polymorphus low-grade neuroepithelial tumor of the young ◦ Diffuse low-grade glioma, MAPK pathway-altered • Circumscribed astrocytic gliomas ◦ Pilocytic astrocytoma ◦ High-grade astrocystoma with piloid features ◦ Pleomorphic xanthoastrocytoma ◦ Subependymal giant cell astrocystoma (SEGA) ◦ Choroid glioma ◦ Astroblastoma, MN • Glioneuronal and neuronal tumors ◦ Gangliоglioneuroma ◦ Desmoplastic infantile gangliоglioneuroma/desmoplastic infantile astrocystoma ◦ Dysembryoplastic neuroepithelial tumor ◦ Diffuse glioneuronal tumor with oligodendroglioma-like features and nuclear clusters ◦ Papillary glioneuronal tumor ◦ Rosette-forming glioneuronal tumor ◦ Myxoid glioneuronal tumor ◦ Diffuse leptomeningeal glioneuronal tumor ◦ Gangliocytoma ◦ Multinodular and vacuolating neuronal tumor ◦ Dysplastic cerebellar gangliocytoma (Lhermitte-Duclos disease) ◦ Central neurocytoma ◦ Extraventricular neurocytoma ◦ Cerebellar liponeurocytoma • Any other glial tumor with a WHO grade I or II classification

General Considerations:

- Account for 40% to 60% of pediatric CNS tumors.
- These tumors are defined as having a WHO grade of I or II (out of IV) and can occur anywhere in the CNS

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Treatment Considerations:

- Children with neurofibromatosis and small optic pathway tumors may not undergo biopsy or resection and will proceed directly to treatment or surveillance
- Children on observation without specific treatment should be imaged according to surveillance guidelines for LGG
- Individuals who undergo complete resection should be imaged according to surveillance guidelines after post-resection imaging
- Individuals age >10 years with incompletely resected tumors usually receive adjuvant radiation therapy
- Individuals age ≤10 years with incompletely resected tumors are commonly treated with chemotherapy

CNS High Grade Gliomas (HGG) (PEDONC-4.3)

ONCP.CT.0004.3.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial staging of all HGG	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2).**
• At any time, for ANY of the following: ◦ For rapid assessment in the acute setting ◦ Evaluation of acute intracranial hemorrhage ◦ Evaluation of ventriculomegaly ◦ Evaluation of shunt-related issues	• CT Head without contrast (CPT® 70450)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• ANY of the following: ◦ Distinguishing radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy ◦ Evaluating inconclusive MRI findings when the PET findings will be used to determine need for biopsy or change in therapy, including a change from active therapy to surveillance ◦ Evaluation of a brain lesion of indeterminate nature when the PET findings will be used to determine whether biopsy/resection can be safely postponed	• PET Brain Metabolic Imaging (CPT® 78608)
• ANY of the following: ◦ To distinguish low grade from high grade gliomas ◦ To evaluate a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed ◦ To distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy	• MR Spectroscopy (MRS, CPT® 76390)
• To depict spatial relationships between eloquent cortex and tumor prior to resection	• Functional MRI (fMRI) (CPT® 70544 or CPT® 70555)
Baseline imaging following resection, to assess degree of resection	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast of resected area, or whole spine if requested (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Treatment response at the completion of radiotherapy	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast of irradiated area, or whole spine if requested (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Treatment response on chemotherapy	• MRI Brain without and with contrast (CPT® 70553) every 2 cycles during active treatment and at the end of planned chemotherapy
Additional treatment response imaging during induction chemotherapy for individuals with measurable spinal cord disease on MRI	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycles
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	• For individuals with intracranial primary: ◦ MRI Brain without and with contrast (CPT® 70553) every 2 months for 1 year, then every 3 months thereafter ◦ MRI Spine is not medically necessary during surveillance in individuals without prior history of spinal involvement except to evaluate symptoms suspicious for spinal cord recurrence • For individuals with a history of spine primary tumor or metastatic spinal involvement: ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 months for 1 year, then every 3 months thereafter • For both brain and spine disease, imaging above may be complemented by MR perfusion and/or MR spectroscopy, and these studies are medically necessary if requested.
Suspected intracranial or intraspinal recurrence	• Utilize criteria listed for initial staging above.
Suspected spinal cord recurrence	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

Includes the following tumors:
• Diffuse midline glioma, H3 K27-altered • Diffuse hemispheric glioma, H3 G34-mutant • Diffuse pediatric-type high-grade glioma, H3-wildtype and IDH-wildtype • Infant-type hemispheric glioma • Any other glial tumor with a WHO grade of III or IV classification

General Considerations:

- Rare in children compared with the adult population, but represent 10% to 20% of pediatric CNS tumors
- Prognosis is very poor, and survival significantly beyond 3 years from diagnosis is rare, even with complete surgical resection at initial diagnosis
- These tumors are defined as having a WHO histologic grade of III or IV (out of IV) can occur anywhere in the CNS (though the majority occur in the brain)

Treatment Considerations:

- Individuals who undergo complete resection should be imaged according to surveillance guidelines after post-resection imaging.
- Individuals with incompletely resected tumors are commonly treated with chemotherapy.

Medulloblastoma (MDB), Other CNS Embryonal Tumors, and Pineoblastoma (PEDONC-4.4)

ONCP.CT.0004.4.A
v2.0.2026

- MR Spectroscopy and PET Brain Metabolic are not medically necessary for routine surveillance.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals, preoperatively	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT®) 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
• At any time, for ANY of the following: ◦ For rapid assessment in the acute setting ◦ Evaluation of acute intracranial hemorrhage ◦ Evaluation of ventriculomegaly ◦ Evaluation of shunt-related issues	• CT Head without contrast (CPT® 70450)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• ANY of the following: ◦ To distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy ◦ To evaluate inconclusive MRI findings when the PET findings will be used to determine need for biopsy or change in therapy, including a change from active therapy to surveillance ◦ To evaluate a brain lesion of indeterminate nature when the PET findings will be used to determine whether biopsy/resection can be safely postponed	• PET Brain Metabolic Imaging (CPT® 78608)
• ANY of the following: ◦ To evaluate a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)
Postoperative (preferably within 48 hours of surgery) to quantify residual tumor volume	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic (CPT® 72157, Lumbar-CPT® 72158) if spinal disease was resected
Within 28 days post-op, if spinal imaging was not performed preoperatively	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Treatment response	• At the start of adjuvant chemotherapy and every 2 cycles until therapy is completed: ◦ MRI Brain without and with contrast (CPT® 70553) ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic CPT® 72157, Lumbar-CPT® 72158)
Children age <3 years treated with multiple cycles of high dose chemotherapy with autologous stem cell rescue in lieu of radiotherapy	• Disease evaluations (imaging per treatment response guidelines) prior to each cycle (every 4 to 6 weeks) if needed for response determination.
End of treatment evaluation	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine with contrast (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) or MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	For low- or average-risk individuals: • Every 3 months for 2 years, then every 6 months for 3 years: ◦ MRI Brain without and with contrast (CPT® 70553) • Every 6 months for 2 years: ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) For high- or very high-risk individuals: • Every 3 months for 2 years, then every 6 months for 3 years: ◦ MRI Brain without and with contrast (CPT® 70553) • Every 3 months for 2 years, then every year for 3 years: ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • For additional imaging guidelines for individuals in long-term follow-up after CNS tumor treatment that included radiation therapy, see: **Second Malignant Neoplasms (SMN) (PEDONC-19.3)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

Includes the Following Tumors:
• Medulloblastoma ◦ Molecularly-defined Medulloblastoma ▪ WNT-activated Medulloblastoma ▪ SHH-activated and TP53-wildtype Medulloblastoma ▪ SHH-activated and TP53-mutant Medulloblastoma ▪ Non-WNT/Non-SHH ◦ Medulloblastoma, histologically defined • Other CNS Embryonal Tumors (previously supratentorial primitive neuro-ectodermal tumors) ◦ CNS embryonal tumor ◦ Cribriform neuroepithelial tumor ◦ Embryonal tumor with multilayered rosettes ◦ CNS neuroblastoma ◦ FOXR2-activated CNS tumor with BCOR internal tandem duplication • Pineoblastoma
Risk Assessment is Important in Determining Optimal Treatment **High-Risk Features Include the Following:**
• Spinal metastasis (including cytology positive only) • Multifocal intracranial tumors • Anaplastic histology • All other CNS embryonal tumors and pineoblastomas • >1.5 cm^2 residual tumor area on postoperative MRI and age <3 years
Individuals without any high-risk features are considered "Average Risk"

General Considerations:

- Account for 15% to 25% of pediatric CNS tumors
- Prognosis is generally favorable
- Leptomeningeal spread is common and can occur after initial diagnosis

Treatment Considerations:

- Individuals generally proceed to chemoradiotherapy within 31 days of surgical resection

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- All individuals receive adjuvant chemotherapy lasting 6 to 12 months that begins ~6 weeks after completion of chemoradiotherapy

Proprietary Information of UnitedHealthcare.

Atypical Teratoid/Rhabdoid Tumors (ATRT) (PEDONC-4.5)

- PET Brain Metabolic does not have a defined role in the evaluation of ATRT at this time and is, therefore, not medically necessary.
- MR Spectroscopy is not medically necessary for routine surveillance.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals, preoperatively	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • Renal US (CPT® 76770) ◦ If renal US is abnormal, refer to: **Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites (PEDONC-7.6)**
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
• At any time, for ANY of the following: ◦ For rapid assessment in the acute setting ◦ Evaluation of acute intracranial hemorrhage ◦ Evaluation of ventriculomegaly ◦ Evaluation of shunt-related issues	• CT Head without contrast (CPT® 70450)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Postoperative (preferably within 48 hours of surgery) to quantify residual tumor volume	• MRI Brain without and with contrast (CPT® 70553)
Within 28 days post-op, if spinal imaging was not performed preoperatively	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Treatment response to induction chemotherapy	• After every 2 cycles: ◦ MRI Brain without and with contrast (CPT® 70553) ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Individuals treated with consolidation chemotherapy and autologous stem cell rescue	• Disease evaluation is medically necessary following the end of the planned stem cell rescues but may occur prior to each cycle (every 4 to 6 weeks) if needed for response determination
End of treatment evaluation	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	• Every 3 months for 2 years, then every 6 months for 3 years, then annually for 10 years: ◦ MRI Brain without and with contrast (CPT® 70553) ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see: **Second Malignant Neoplasms (SMN) (PEDONC-19.3)**

Background and Supporting Information:

General Considerations

- Highly aggressive tumor occurring primarily in very young children that has a clinical presentation very similar to medulloblastoma with a much higher rate of leptomeningeal spread.
- Metastases can occur outside the CNS, and associated tumors can also arise in the kidneys (Malignant Rhabdoid Tumor of the Kidney, MRT).
  - Rhabdoid malignancies occurring outside the CNS should be imaged according to **Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites (PEDONC-7.6)**.
- Overall prognosis is poor, with <20% of individuals surviving beyond 2 years from diagnosis.
- Individuals generally proceed to induction chemotherapy shortly following surgical resection or biopsy.
- Following completion of chemotherapy some individuals will proceed to radiotherapy.
  - MRI performed at the end of consolidation therapy should serve as the diagnostic MRI prior to radiotherapy.

Pineocytomas and Pineal Parenchymal Tumors (PEDONC-4.6)

ONCP.CT.0004.6.A

v2.0.2026

- PET Brain Metabolic imaging and MR Spectroscopy do not have a defined role in the evaluation of pineocytoma.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• MRI Brain without and with contrast (CPT® 70553)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
• Additional initial staging imaging for individuals with: ◦ Multicentric tumors ◦ Atypical histology including pineoblastoma-like elements (grade 2 or 3 pineal parenchymal tumor which have not been considered a pineoblastoma) ◦ Clinical signs or symptoms suggesting spinal cord involvement	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Baseline imaging following resection	• MRI Brain without and with contrast (CPT® 70553)
End of radiotherapy	• MRI Brain without and with contrast (CPT® 70553)
Additional imaging at end of radiotherapy for individuals with measurable spinal cord disease on MRI	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	• MRI Brain without and with contrast (CPT® 70553) every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually thereafter
Additional surveillance imaging for individuals with cord involvement at diagnosis	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) after completion of therapy every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually thereafter
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553)
Suspected spinal cord recurrence or progression	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Background and Supporting Information

General Considerations:

- Low grade malignancy that is similar in presentation to low grade glioma (LGG)
- Surgical resection is curative for most individuals
- Individuals with a complete resection should then be imaged according to surveillance guidelines
- Individuals with incompletely resected tumors may receive adjuvant radiation therapy
- After end of radiotherapy imaging, these individuals should be imaged according to surveillance guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CNS Germinomas and Non-Germinomatous Germ Cell Tumors (NGGCT) (PEDONC-4.7)

ONCP.CT.0004.7.A
v2.0.2026

- PET Metabolic Brain imaging does not have a defined role in the evaluation of CNS GCT and is, therefore, considered not medically necessary.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
• At any time, for ANY of the following: ◦ For rapid assessment in the acute setting ◦ Evaluation of acute intracranial hemorrhage ◦ Evaluation of ventriculomegaly ◦ Evaluation of shunt-related issues	• CT Head without contrast (CPT® 70450)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)
Treatment response to induction chemotherapy	• MRI Brain without and with contrast (CPT® 70553) every 2 cycles

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Additional treatment response to induction chemotherapy for individuals with measurable spinal cord disease on MRI	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycles
End of induction chemotherapy for individuals with localized intracranial tumors	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Prior to second-look surgery	• MRI of all known sites of measurable disease
Prior to radiotherapy	• MRI of all known sites of measurable disease
At the end of all planned therapy	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine (with or without and with contrast)
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Surveillance	• Every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually until 5 years after completion of therapy: ◦ MRI Brain without and with contrast (CPT® 70553) ◦ MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see: **Second Malignant Neoplasms (SMN) (PEDONC-19.3)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Suspected recurrence - new or worsening neurologic symptoms (including worsening of diabetes insipidus)	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Background and Supporting Information

Includes the following tumors:
• CNS Germinoma • Non-Germinomatous Germ Cell Tumors (NGGCT) ◦ Embryonal carcinoma ◦ Yolk sac tumor ◦ Choriocarcinoma ◦ Immature Teratoma ◦ Mature Teratoma ◦ Mixed germ cell tumor

General Considerations:

- More common in older school age children and younger adolescents, but can occur throughout the pediatric age range
- Although leptomeningeal spread is common, prognosis is excellent due to high sensitivity to chemotherapy and radiotherapy
- Individuals generally proceed to chemotherapy shortly following surgical resection or biopsy and will usually receive 2 - 4 cycles
- Following completion of chemotherapy, individuals with residual disease will proceed to second-look surgery and/or radiotherapy

Proprietary Information of UnitedHealthcare.

Ependymal Tumors (Ependymoma) (PEDONC-4.8)

ONCP.CT.0004.8.A

v2.0.2026

- PET Brain Metabolic imaging does not have a defined role in the evaluation of ependymal tumors and therefore is considered not medically necessary.
- MR Spectroscopy is not medically necessary for routine surveillance

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)
Baseline imaging following resection	• MRI Brain without and with contrast (CPT® 70553) or MRI without and with contrast of involved spinal level(s)
Completion of radiotherapy	• MRI Brain without and with contrast (CPT® 70553) or MRI without and with contrast of involved spinal level(s)
Prior to radiotherapy	• MRI of all known sites of measurable disease
Treatment response to induction chemotherapy	• MRI Brain without and with contrast (CPT® 70553) or MRI without and with contrast of involved spinal level(s) every 2 cycles

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
End of induction chemotherapy and again at end of all therapy	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Prior to second-look surgery	• MRI of all known sites of measurable disease
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Surveillance, primary intra**cranial** ependymal tumor and NO history of spinal cord involvement	• MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment ◦ For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see: **Second Malignant Neoplasms (SMN) (PEDONC-19.3)** • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) can be approved annually for 2 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Surveillance, primary intra**cranial** ependymal tumor AND metastatic cord involvement at diagnosis	• MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment ◦ For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see: **Second Malignant Neoplasms (SMN) (PEDONC-19.3)** • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment
Surveillance, primary intra**spinal** ependymal tumor and NO history of intracranial involvement	• MRI without and with contrast of the involved spinal level(s) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment
Surveillance, primary intra**spinal** ependymal tumor AND metastatic intracranial involvement at diagnosis	• MRI of the involved spinal level(s) without and with contrast every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment • MRI Brain without and with contrast (CPT® 70553) every 3 months for 2 years, then every 4 months for 1 year, then every 6 months in years 4 and 5, then annually to 10 years post treatment

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

Includes the following tumors:

- Ependymal tumors
  - Supratentorial ependymoma
  - ZFTA fusion-positive Supratentorial ependymoma
  - YAP1 fusion-positive Posterior fossa ependymoma
  - Posterior fossa ependymoma, group
  - PFA Posterior fossa ependymoma, group PFB

General Considerations:

- Occur primarily intracranially, roughly two-thirds in the posterior fossa
- Overall prognosis is very good, with supratentorial tumors faring better
- Primary spinal tumors can also occur, and are more common in adult individuals than pediatric individuals.
- Surgery is the primary treatment modality
- Individuals with a complete resection should then be imaged according to surveillance guidelines
- Radiotherapy +/- chemotherapy is used for:
  - Incompletely resected tumors
  - Anaplastic histology
  - Infratentorial location
    - Individuals with incomplete resection or high-risk histology that receive adjuvant radiation therapy should then be imaged according to surveillance guidelines after end of radiotherapy imaging.
- Individuals with gain of chromosome 1q have worse progression-free survival and overall survival outcomes
- RELA-fusion supratentorial ependymoma did not portend worse overall survival outcomes in recent Clinical Oncology Group studies, and is generally not considered an indication for more frequent surveillance imaging

Proprietary Information of UnitedHealthcare.

Malignant Tumors of the Spinal Cord (PEDONC-4.9)

ONCP.CT.0004.9.A
v2.0.2026

- If a disease-specific guideline exists, image according to the guidance found in that disease-specific guideline section.
- Common histologies of primary spinal cord tumor in children include:
  - Low-Grade Glioma, see: **CNS Low Grade Glioma (LGG) (PEDONC-4.2)** for guidelines
  - High-Grade Glioma, see: **CNS High-Grade Glioma (HGG) (PEDONC-4.3)** for guidelines
  - Ependymoma, see: **Ependymal Tumors (Ependymoma) (PEDONC-4.8)** for guidelines
  - NF 1 or 2, see **Neurofibromatosis 1 and 2 (NF1 and NF2) (PEDONC-2.3)** for guidelines
  - Any type of malignant spinal cord tumor can occur, but other histologies are rare.

For rare histologies that do not have a disease-specific guideline section, follow the imaging outlined in the table below.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
Treatment response, every 2 cycles	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • Additionally, MRI Brain without and with contrast (CPT® 70553) for known intracranial disease

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Signs or symptoms of recurrence or progression	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) • Additionally, MRI Brain without and with contrast (CPT® 70553) for known intracranial disease
Surveillance of rare histologies is highly individualized. Surveillance imaging after recent evaluation by a physician with significant training and/or experience in pediatric spinal cord tumors (most commonly a pediatric neurosurgeon or pediatric oncologist) may be indicated in these rare individuals.	• MRI Brain and/or MRI Spine may be considered

Background and Supporting Information

- Treatment principles are the same as tumors of the brain, and should follow imaging guidelines according to the specific histologic type
- Multiple spinal cord tumors should raise suspicion for neurofibromatosis
- Asymptomatic surveillance imaging should generally end at the time point appropriate for the specific tumor type

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Craniopharyngioma and Other Tumors of the Sellar Region (PEDONC-4.10)

ONCP.CT.0004.10.A
v2.0.2026

- Individuals of all ages should be imaged according to these guidelines.
- PET Brain Metabolic Imaging and MR Spectroscopy do not have a defined role in the evaluation of craniopharyngioma and are, therefore, considered not medically necessary.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• MRI Brain without and with contrast (CPT® 70553) ◦ Concurrent CT Head without contrast (CPT® 70450) in addition to MRI if craniopharyngioma is suspected
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
• Additional initial staging for individuals with: ◦ Multicentric tumors ◦ Clinical signs or symptoms suggesting spinal cord involvement	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Operative planning or image guidance	• MRA Head (CPT® 70544, 70545, or 70546) OR • CTA Head (CPT® 70496)
Baseline imaging following resection	• MRI Brain without and with contrast (CPT® 70553)
Completion of radiotherapy	• MRI Brain without and with contrast (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Treatment response to chemotherapy	• MRI Brain without and with contrast (CPT® 70553) approved every 2 cycles during active treatment and at the end of planned chemotherapy
Additional treatment response imaging during induction chemotherapy for individuals with measurable spinal cord disease on MRI	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycles
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) ◦ Concurrent CT Head without contrast (CPT® 70450) in addition to MRI for craniopharyngioma • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) for signs or symptoms suggesting spinal cord involvement
Surveillance	• MRI Brain without and with contrast (CPT® 70553) can be approved every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually until 10 years after completion of therapy as late progressions can occur ◦ For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see **Second Malignant Neoplasms (SMN) (PEDONC-19.3)**.
Suspected spinal cord recurrence	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

Includes the following tumors:
• Craniopharyngioma • Papillary craniopharyngioma • Pituicytoma, granular cell tumor of the sellar region, and spindle cell oncocytoma • PitNET • Pituitary blastoma

General Considerations:

- Imaging guidelines and treatment approaches for pediatric pituitary tumors other than those listed above are consistent with those used for adults with pituitary tumors.
  - For these tumors, follow guidelines in **Pituitary, Sella, Hypothalamus (HD-19)** in the Head Imaging Guidelines.
- Craniopharyngiomas are less common, accounting for 6% to 8% of pediatric CNS tumors.
- Most commonly affects children in the pre-adolescent ages
- Several key imaging findings can be used to differentiate the tumors in this region, including the presence of calcifications, cysts, and T1/T2 enhancement patterns in craniopharyngiomas .
  - These are best evaluated using a COMBINATION of both MRI and CT modalities. Preoperative prediction is much more successful when BOTH modalities are obtained prior to biopsy.
- Other less common tumors in the optic chiasm, sella, and suprasella region may include Germ Cell Tumors (GCT, see: **PEDONC-4.7**) and Langerhans Cell Histiocytosis (LCH, see: **PEDONC-18**).

Treatment Considerations:

- Surgical resection is curative for many individuals
  - Those with a complete resection should then be imaged according to surveillance guidelines after post-resection imaging is completed.
- Individuals with incomplete resection and receiving adjuvant radiation therapy can have a single MRI Brain (CPT® 70553) approved at completion of radiotherapy and should then be imaged according to surveillance guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Primary CNS Lymphoma (PEDONC-4.11)

ONCP.CT.0004.11.A
v2.0.2026

- Primary CNS lymphoma imaging indications in pediatric individuals are identical to those in the general imaging guidelines. See: **CNS Lymphoma (ONC-2.7)** in the Oncology Imaging Guidelines.
- CNS lymphomas also involving bone marrow and/or lymph nodes should be imaged according to: **Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL) (PEDONC-5.3)**.

Background and Supporting Information

- Primary CNS lymphoma is a solitary or multifocal mass occurring in the brain without evidence of systemic (bone marrow or lymph node) involvement.
- Usually associated with immunodeficiency, this is a very rare entity in pediatrics accounting for <0.1% of pediatric malignancies, so age-specific guidelines have not been established.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Meningiomas (PEDONC-4.12)

ONCP.CT.0004.12.A

v2.0.2026

- Meningioma imaging indications in pediatric individuals are identical to those in the general imaging guidelines
  - See: **Meningiomas (Intracranial and Intraspinal) (ONC-2.8)** in the Oncology Imaging Guidelines

Background and Supporting Information

- Account for 1% to 3% of pediatric CNS tumors
- Usually associated with neurofibromatosis type 2 (NF-2) or prior therapeutic radiation exposure to the brain
  - Lifetime risk may be as high as 20% for young children receiving whole brain radiotherapy, most commonly occurring 15 to 20 years after radiation exposure.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Choroid Plexus Tumors (PEDONC-4.13)

ONCP.CT.0004.13.A
v2.0.2026

- PET Metabolic Brain imaging does not have a defined role in the evaluation of choroid plexus tumors and is, therefore, considered not medically necessary.

Choroid Plexus Papilloma:

Indication	Medically Necessary Imaging Study
Suspected/Diagnosis	• MRI Brain without and with contrast (CPT® 70553)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to **Neuronavigation (HD-28.2)**
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)
Suspected return of hydrocephalus, or return of hydrocephalus seen on CT imaging	• MRI Brain without and with contrast (CPT® 70553)

Choroid Plexus Adenoma or Atypical Choroid Plexus Papilloma:

Indication	Medically Necessary Imaging Study
Suspected/Diagnosis	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to Neuronavigation (HD-28.2)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)
Suspected return of hydrocephalus, or return of hydrocephalus seen on CT imaging	• MRI Brain without and with contrast (CPT® 70553)

Choroid Plexus Carcinoma:

Indication	Medically Necessary Imaging Study
Initial staging of all individuals	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
In addition to the above imaging, for preoperative planning	• Functional MRI (fMRI) (CPT® 70555 or 70554) • For further perioperative indications, please refer to Neuronavigation (HD-28.2)
Evaluation of a brain lesion of indeterminate nature when the MRS findings will be used to determine whether biopsy/resection can be safely postponed	• MR Spectroscopy (CPT® 76390)
Baseline imaging following resection	• MRI Brain without and with contrast (CPT® 70553)
Prior to radiotherapy	• MRI Brain without and with contrast (CPT® 70553) and MRI with and without contrast of all known sites with measurable disease prior to radiotherapy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Completion of radiotherapy	• MRI Brain without and with contrast (CPT® 70553)
Treatment response to chemotherapy	• MRI Brain without and with contrast (CPT® 70553) every 2 cycles during active treatment
Additional treatment response to chemotherapy for individuals with measurable spinal cord disease on MRI	• MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 2 cycles during active treatment
Prior to second-look surgery	• MRI of all known sites of measurable disease
End of all planned therapy	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Signs or symptoms of recurrence or progression	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Surveillance, no history of spinal cord involvement	• MRI Brain without and with contrast (CPT® 70553) every 4 months for 3 years, then every 6 months for 2 years after completion of therapy, then annually to 10 years after treatment ◦ For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see **Second Malignant Neoplasms (SMN) (PEDONC-19.3)**. • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) at 12 and 24 months after completion of therapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance, individuals with cord involvement at diagnosis	• MRI Brain without and with contrast (CPT® 70553) every 4 months for 3 years, then every 6 months for 2 years after completion of therapy, then annually to 10 years after treatment ◦ For additional imaging guidelines for individuals in long term follow up after CNS tumor treatment that included radiation therapy, see **Second Malignant Neoplasms (SMN) (PEDONC-19.3).** • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) every 4 months for 3 years, then every 6 months for 2 years after completion of therapy, then annually to 10 years after treatment

Background and Supporting Information

As a group,choroid plexus papilloma, choroid plexus carcinoma and choroid plexus adenoma, or atypical choroid plexus papilloma account for 1% to 4% of pediatric CNS tumors, and 70% of choroid plexus tumors present within the first 2 years of life:

- Choroid plexus papillomas
  - Choroid plexus papillomas outnumber other choroid plexus tumors by 4 to 5 times.
  - These ventricular tumors commonly present with hydrocephalus caused by increased CSF production, resulting in signs of increased intracranial pressure.
  - Appearance on MRI is typical, and they are usually treated by excision.
  - Regrowth is rare.
- Choroid Plexus Adenoma or Atypical Choroid Plexus Papilloma
  - These are extremely rare tumors with features midway in the malignant spectrum between papillomas and carcinomas .
  - They are more prone to local invasion but rarely to metastasis .
  - Presenting symptoms are similar to papillomas .
  - Appearance on MRI is typical, and they are usually treated by excision.
  - Spinal imaging may be approved if requested at initial diagnosis.
  - Regrowth is rare.
- Choroid Plexus Carcinoma
  - This is a very aggressive malignancy, with high rates of metastasis to other parts of the CNS .

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - Overall incidence of metastases in choroid plexus carcinoma is 12%–50%, which is associated with a worse outcome.
  - Prognosis is significantly less favorable than for papillomas with overall survival rates of 35% to 40%
  - *TP53* mutations and alternative lengthening telomeres (ALT) are common in individuals with choroid plexus carcinoma .
  - Surgical gross total resection is curative for many individuals.
  - Individuals with confirmed gross total resection should then be imaged according to surveillance guidelines.
  - Individuals with incomplete resection who receive adjuvant radiation therapy should be imaged according to surveillance guidelines after end of radiotherapy imaging.
  - MR Spectroscopy is not indicated for routine surveillance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Pediatric Lymphoma – General Considerations (PEDONC-5.1)

ONCP.HL.0005.1.A
v2.0.2026

- Lymphoma mostly commonly involves the lymph nodes (LNs). However, lymphoma can also arise from primary lymphoid tissues (bone marrow or thymus) or various secondary lymphoid tissues (spleen, mucosa-associated lymphoid tissue) or non-lymphoid organs (skin, bone, brain, lungs, liver, salivary glands, etc.).
- Pediatric lymphomas are generally Hodgkin Lymphomas, Aggressive B-Cell Non-Hodgkin Lymphomas, Lymphoblastic Lymphomas, or Anaplastic Large Cell Lymphomas
- Individuals with Lymphoblastic Lymphoma (even those with bulky nodal disease) are treated using the leukemia treatment plan appropriate to the cell type (B or T cell).
  - These individuals should be imaged using guidelines in **Acute Lymphoblastic Leukemia (ALL) (PEDONC-3.2)**
- Other histologies are rare in pediatric individuals, and should be imaged according to the following guidelines:
  - Follicular lymphoma: **Follicular Lymphoma (ONC-27.3)** in the Oncology Imaging Guidelines
  - Marginal zone or MALT lymphomas: **Marginal Zone Lymphomas (ONC-27.4)** in the Oncology Imaging Guidelines
  - Mantle cell lymphomas: **Mantle Cell Lymphoma (ONC-27.5)** in the Oncology Imaging Guidelines
  - Cutaneous lymphomas: **Cutaneous Lymphomas and T Cell Lymphomas (ONC-27.8)** in the Oncology Imaging Guidelines
    - **Exception:** Cutaneous B-Lymphoblastic Lymphoma should be imaged using guidelines in **Acute Lymphoblastic Leukemia (ALL) (PEDONC-3.2)**
  - Castleman's Disease: **Castleman's Disease (Unicentric and Multicentric) (ONC-31.11)** in the Oncology Imaging Guidelines
- All CT imaging recommended in this section refers to CT with contrast only.
  - Noncontrast CT imaging has not been shown to be beneficial in the management of pediatric lymphomas
  - Given the limited utility of noncontrast CT imaging in pediatric lymphomas, MRI without **or** without and with contrast is recommended in place of CT for individuals who cannot tolerate CT contrast due to allergy or impaired renal function.
- MRI without and with contrast of symptomatic or previously involved bony areas is medically necessary in individuals with known lymphoma without prior plain x-ray or bone scan evaluation.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Bone scan is inferior to MRI for evaluation of known or suspected bone metastases in lymphoma.
- MRI Brain without and with contrast (CPT® 70553) is medically necessary as it is the preferred study for evaluation of suspected brain metastases in pediatric lymphoma.
  - CT Head with (CPT® 70460) or without and with contrast (CPT® 70470) is medically necessary when MRI is contraindicated.

Pediatric Hodgkin Lymphoma (HL) (PEDONC-5.2)

ONCP.HL.0005.2.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial staging	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) ◦ MRI Neck without and with contrast (CPT® 70543) as a substitute for CT to limit radiation exposure if requested • CT Chest with contrast (CPT® 71260) ◦ MRI is not a substitution for CT Chest • CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast as substitute for CT to limit radiation exposure if requested • MRI Brain without and with contrast (CPT® 70553) for known CNS involvement or new signs or symptoms suggesting intracranial disease • PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) ◦ Can be performed prior to biopsy if necessary for individual scheduling • CT or MRI of other body areas may be indicated for rare individuals based on physical findings or PET/CT results

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Restaging	• ALL of the following, as often as every 2 cycles of chemotherapy: ◦ CT of previously involved visceral areas ▪ In individuals on treatment for recurrent or refractory Hodgkin Lymphoma, all of the following: - CT Neck with contrast (CPT® 70491) - CT Chest with contrast (CPT® 71260) - CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Brain without and with contrast (CPT® 70553) for known CNS involvement AND • After cycles 2 and 4* of chemotherapy and at end of therapy: ◦ PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (only using combination of CPT® 78813 and 76498) ▪ *For individuals with low-risk stage IA or IIA mixed cellularity Hodgkin lymphoma, this restaging PET/CT is medically necessary after cycles 1 and 3 (instead of cycles 2 and 4) if requested. End of therapy PET/CT or PET/MRI is medically necessary for all individuals with Hodgkin lymphoma. ◦ Diagnostic CT or MRI of previously involved areas may be combined with PET at end of therapy. • In addition to the above studies: ◦ If end of therapy PET/CT or PET/MRI done prior to radiation therapy documents Deauville 4 or 5 FDG avidity, one follow-up PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI is medically necessary >12 weeks after radiation therapy to confirm complete response.
Surveillance for individuals with no history of recurrent HL	• Imaging studies are only medically necessary when relapse is clinically suspected, because most individuals will clinically declare themselves and there is no survival advantage in pre-emptive imaging. • **Routine surveillance imaging is not medically necessary in individuals without a prior history of recurrent disease**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance, individuals with **recurrent** HL and no evidence of disease following successful treatment	• ALL of the following, every 3 months for 2 years after completing therapy for recurrence: ◦ CT Neck with contrast (CPT® 70491) ◦ CT Chest with contrast (CPT® 71260) ◦ CT Abdomen and Pelvis with contrast (CPT® 74177)
Clarify inconclusive findings on conventional imaging suspicious for recurrence AND considering biopsy to establish recurrence	• PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498)
Clinical symptoms suggesting recurrence	• MRI Brain with and without contrast (CPT® 70553) for known CNS involvement or new signs or symptoms suggesting intracranial disease AND either of the following sets of imaging: • Conventional imaging: ◦ CT Neck with contrast (CPT® 70491) OR MRI Neck without and with (CPT® 70491) AND ◦ CT Chest with contrast (CPT® 71260) AND ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) OR MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) AND ◦ CT of other previously involved visceral areas or currently symptomatic areas OR • PET/CT (CPT® 78815 or 78816) or PET/MRI (CPT® 78813 and CPT® 76498)

Background and Supporting Information

- Most individuals experiencing recurrence are detected based on physical findings, and frequent CT surveillance imaging of Hodgkin Lymphoma after completion of therapy does not improve post-recurrence overall survival. The primary determinant of survival at recurrence is time to relapse, regardless of whether relapse is detected

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

clinically or via imaging. NCCN pediatric HL guidelines recommend no pre-emptive surveillance imaging.

- Pediatric individuals have a high rate of neck involvement with Hodgkin Lymphoma
- Early treatment response evaluations involve both PET and CT as decisions about chemotherapy drug selection and radiation treatment are frequently made based on both anatomic (CT-based) and metabolic (PET/CT-based) responses.
- Indications and coding for rare circumstances where PET/MRI may be approved are found in **PET imaging in Pediatric Oncology (PEDONC-1.4)**

Proprietary Information of UnitedHealthcare.

Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL) (PEDONC-5.3)

ONCP.HL.0005.3.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial staging	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) ◦ MRI Neck without and with contrast (CPT® 70543) in place of CT Neck, if requested • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) in place of CT Abdomen and Pelvis, if requested. ◦ Abdominal ultrasound (CPT® 76700 or 76705) at initial presentation if CT/MRI not available. • CT with contrast or MRI without and with contrast any other symptomatic body area • PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498 [may be approved in addition to diagnostic CTs])
Additional initial staging if symptoms or extent of disease suggest intracranial extension or metastasis	• MRI Brain without and with contrast (CPT® 70553)
Additional initial staging if symptoms or extent of disease suggest intraspinal extension or metastasis (back pain)	• MRI of suspected spinal level involvement without and with contrast • MRI of whole spine without and with contrast if there is suspected leptomeningeal disease or if sedation will be required

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Restaging for treatment response	• **ANY** of the following, as often as every cycle of chemotherapy (~every 3 weeks): ◦ CT with contrast or MRI without and with contrast (should be same modality as initial diagnosis if possible) of previously involved areas ◦ PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) until a negative PET is obtained ▪ Whole-body PET/CT (CPT® 78816) may be approved if there is clinical suspicion of, or known, skull or distal lower extremity involvement. ▪ PET/CT may be approved in conjunction with diagnostic CTs/MRIs, PET/CT should not replace imaging with contrast-enhanced diagnostic-quality CT or MRI.
Restaging for all subsequent treatment response, including end of therapy evaluation, after negative PET/CT (either Deauville or Lugano 1, 2 or 3 as reported in formal radiology interpretation)	• CT with contrast or MRI without and with contrast (should be same modality as initial diagnosis if possible) of previously involved areas, as often as every 2 cycles of chemotherapy, and at the end of therapy
End of therapy PET with Deauville 4-5 avidity	ONCE, at least 6-8 weeks after end of therapy PET: • PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) OR • CT Neck, Chest, Abdomen, and Pelvis with contrast (CPT® 70491, CPT® 71260, CPT® 74177)
Assessment of disease activity in inconclusive residual masses seen on conventional imaging	• PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Individuals being treated with Rituximab who present with abdominal pain, due to risk of bowel perforation and obstruction	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ US, x-ray, or other red flags are not required prior to CT
Surveillance of asymptomatic individuals with residual masses in the chest or abdomen and pelvis	• Chest x-ray and Abdominal (CPT® 76700) and Pelvic (CPT® 76856) ultrasound 3 months after completion of therapy. If stable, no further imaging.
Clinical symptoms or laboratory findings suggesting recurrence	• MRI Brain without and with (CPT® 70553) for history of CNS involvement or new signs or symptoms suggesting intracranial disease In addition to the above imaging, **ANY** of the following: • CT Neck with contrast (CPT® 70491) **and** CT Chest with contrast (CPT® 71260) **and** CT Abdomen and Pelvis with contrast (CPT® 74177) **and** CT with contrast of other previously involved visceral areas or currently symptomatic areas (MRI with and without contrast in place of CT for all areas other than the chest if requested) **and** • PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498)
Suspected PTLD recurrence with documentation of new palpable nodes, rising LDH, or rising quantitative EBV PCR	• PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498)

Background and Supporting Information

- Aggressive mature B-Cell NHL includes all of the following diagnoses, all of which should be imaged according to this section:
  - Burkitt's lymphoma/leukemia (BL)
  - Diffuse Large B-Cell Lymphoma (DLBCL)
  - Primary Mediastinal Large B-Cell Lymphoma (PMBCL)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Post-transplant Lymphoproliferative Disorder (PTLD)
    - most commonly occurs following solid organ or stem cell transplantation.
  - Viral-associated lymphoproliferative disorders
    - most commonly occurs following hematopoietic stem cell transplantation or in individuals with primary immunodeficiency.
- Initial treatment is usually 7 days of low intensity therapy, with early response evaluation determining next steps in therapy using CT with contrast or MRI without and with contrast of previously involved areas performed around day 6
  - Individuals are customarily still inpatient for this evaluation so outpatient requests should be rare for this time point.
- Routine asymptomatic surveillance with advanced imaging has not been found to impact individual outcomes as the majority of these individuals present clinically at relapse due to the highly aggressive nature of these lymphomas.
- Indications and coding for rare circumstances where PET/MRI may be approved are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4).**

Proprietary Information of UnitedHealthcare.

Anaplastic Large Cell Lymphoma (ALCL) (PEDONC-5.4)

ONCP.HL.0005.4.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial staging	• ANY OR ALL of the following: ◦ CT Neck with contrast (CPT® 70491), CT Chest with contrast (CPT® 71260), and CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI without and with contrast of affected area ▪ Substituted for CT in cases of paraspinal or soft tissue extremity primary tumors ◦ CT with contrast or MRI without and with contrast any other symptomatic body area ◦ PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and 76498)
Additional initial staging for individuals with bony primary tumors or metastatic disease	• Bone scan (See: **Modality General Considerations (PEDONC-1.3)**)
Restaging at the end of induction chemotherapy (commonly 4 to 6 weeks)	• CT with contrast or MRI without and with contrast of previously involved areas (should be same modality as initial diagnosis if possible)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Treatment response in individuals treated with cytotoxic chemotherapy	• Every 2 cycles: ◦ CT of previously involved areas ▪ If CT is performed for primary treatment response, PET/CT (CPT® 78815 or CPT® 78816) to clarify inconclusive findings detected on conventional imaging OR ◦ PET/CT or PET/MRI (CPT® 78813 and CPT® 76498) until a negative PET is obtained ▪ If PET/CT (CPT® 78815 or CPT® 78816) is performed for primary treatment response, CT or MRI to clarify inconclusive findings detected on PET imaging
Restaging after negative PET/CT (either Deauville or Lugano 1, 2 or 3 as reported in formal radiology interpretation)	• CT with contrast of previously involved areas
Surveillance	• CT with contrast or MRI without and with contrast of all previously involved areas every 6 months for 2 years after completion of therapy.
Additional surveillance for individuals with bony primary tumors or metastatic disease	• Bone scan (See: **Modality General Considerations (PEDONC-1.3)** for coding) at 3, 6, 12, and 18 months after therapy is completed
Clinical symptoms suggesting recurrence	• CT Neck with contrast (CPT® 70491), CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and CT with contrast of other previously involved or currently symptomatic areas
Clarify inconclusive findings on conventional imaging to evaluate the need for biopsy to establish recurrence	• PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Neuroblastoma – General Considerations (PEDONC-6.1)

ONCP.NP.0006.1.A
v2.0.2026

- PEDONC-6 should be used to review neuroblastoma, ganglioneuroblastoma, and ganglioneuroma in individuals of all ages, with the exception of esthesioneuroblastoma in individuals of all ages, which should be reviewed using **Squamous Cell Carcinomas of the Head and Neck (ONC-3)** in the Oncology Imaging Guidelines.
- Neuroblastoma is divided into very low, low, intermediate, and high-risk disease based on International Neuroblastoma Risk Group (INRG) Staging System (see: **Staging and Risk Grouping (PEDONC-6.2)**). The treatment approaches for each risk group vary widely and have distinct imaging strategies. The risk group for a given individual should be provided by the ordering provider in the clinical information provided for review.
- For metabolic imaging in individuals who are MIBG positive at diagnosis and then become MIBG negative in response to treatment:
  - Continue to use MIBG (see table below and **PEDONC-1.3** for coding)

Study Type	Coding
Bone scan	▪ **ANY** of the following codes are medically necessary : - CPT® 78300 - CPT® 78305 - CPT® 78306 - CPT® 78803, 78830, or 78832 • In addition to the above imaging, **ANY** of the following are medically necessary : ◦ CPT® 78305 ◦ CPT® 78306

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Study Type	Coding
^{123}I-metaiodobenzylguanidine (MIBG) scintigraphy	▪ **ONE** of the following codes is medically necessary: : - CPT® 78801 - CPT® 78802 - CPT® 78804 ▪ In addition to the above imaging, **ONE** of the following is medically necessary: - CPT® 78803 - CPT® 78830 - CPT® 78831 - CPT® 78832 **OR** ▪ CPT® 78800 is medically necessary for KNOWN neuroblastoma when only a single-site follow up is desired but is not sufficient for the initial workup of suspected disease.
Octreotide scan	▪ Same coding as MIBG
Gallium scan	▪ Same coding as MIBG

- MIBG remains the standard of care metabolic imaging in neuroblastoma. 18F-FDG-PET-CT is not medically necessary unless one of the exceptions below is present. **All PET imaging in PEDONC-6 refers to 18F-FDG radiotracer.** All other radiotracers are considered not medically necessary at this time:

Indication	Medically Necessary Imaging Study
◦ Any of the following: ▪ individuals with MIBG-negativity documented at initial diagnosis ▪ individuals with discordant findings on MIBG and conventional imaging (i.e., it is suspected there is more active disease than is visible on MIBG) ▪ at major decision points (such as hematopoietic stem cell transplant or surgery), if MIBG and CT/MRI findings are inconclusive	◦ Whole-body 18F-FDG PET/CT (CPT® 78816) ◦ In scenarios where PET/CT is supported, it does not preclude the other diagnostic imaging studies supported throughout **PEDONC-6**. PET/CT is viewed as replacing MIBG in these scenarios. Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
◦ Individuals currently receiving medications that may interfere with MIBG uptake that cannot be safely discontinued prior to imaging, including: ▪ tricyclic antidepressants (amitriptyline, imipramine, etc.) ▪ selective serotonin reuptake inhibitors (SSRI's, sertraline, paroxetine, escitolapram, etc.) ▪ neuroleptics (risperidone, haloperidol, etc.) ▪ antihypertensive drugs (alpha or beta blockers, calcium channel blockers) ▪ decongestants (phenylephrine, ephedrine, pseudoephedrine) ▪ stimulants (methylphenidate, dextroamphetamine, etc.)	◦ 18F-FDG PET/CT (CPT® 78816) is only medically necessary when specific documentation of the medication interaction is included with the current PET imaging request. ◦ Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**

Background and Supporting Information

- Neuroblastoma is the most common extracranial solid tumor of childhood, and generally arises from the adrenal gland or along the sympathetic chain. Neuroblastoma staging has recently changed to better incorporate the prognostic impact of biological and genetic characteristics, particularly segmental chromosome aberrations (SCA) as an additional genomic marker. SCAs of 1p or 11g are poor prognostic indicators.
- 90% to 95% of neuroblastomas secrete homovanillic acid (HVA) and vannilylmandelic acid (VMA) in the urine, and urine HVA/VMA should be performed at every disease evaluation for individuals with positive HVA or VMA at diagnosis.
- 99mTc-MDP bone scan does not identify foci of disease that affect staging or clinical management and provides no advantage over MIBG scintigraphy and is not used for evaluation of most individuals with neuroblastoma.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Staging and Risk Grouping – Neuroblastoma (PEDONC-6.2)

- Most recent treatment protocols are using the updated International Neuroblastoma Risk Group (INRG) staging system
  - L1: Localized tumor not involving vital structures as defined by the list of image-defined risk factors and confined to one body compartment
    - Image-defined risk factors include a list of specific imaging findings defining individuals less likely to be candidates for complete surgical resection
    - These risk factors involve the encasement of major blood vessels, airway, skull base, costovertebral junction, brachial plexus, spinal canal, or major organs or structures
  - L2: Locoregional tumor with presence of one or more image-defined risk factors
  - M: Distant metastatic disease (except stage MS)
  - MS: Metastatic disease in children younger than 18 months with metastases confined to skin, liver, and/or bone marrow with <10% involvement (MIBG must be negative in bone and bone marrow)
- The risk group for any given individual should be provided or documented by the requesting provider.

Proprietary Information of UnitedHealthcare.

Neuroblastoma – Initial Staging (PEDONC-6.3)

ONCP.NP.0006.3.A
v2.0.2026

The following imaging studies are medically necessary in the initial staging of individuals with neuroblastoma, ganglioneuroblastoma, or ganglioneuroma:

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• ^{123}I-metaiodobenzylguanidine scintigraphy (see table in **Neuroblastoma – General Considerations (PEDONC-6.1)** for MIBG coding details) AND • ONE of the following sets of imaging: ◦ CT Neck with contrast (CPT® 70491), CT Chest with contrast (CPT® 71260), and CT Abdomen and Pelvis with contrast (CPT® 74177) OR • MRI Neck without and with contrast (CPT® 70543), MRI Chest without and with contrast (CPT® 71552), and MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
• All individuals with paraspinal tumors • Individuals with back pain or cord compression symptoms	In addition to the above imaging: • MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar (CPT® 72158) spine without and with contrast
Evaluation of suspected adrenal neuroblastoma, ganglioneuroblastoma, or ganglioneuroma when CT or MRI is inconclusive for an adrenal lesion.	• Adrenal nuclear imaging (CPT® 78075)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Clinical signs/symptoms suggest brain and/or orbital involvement	**ANY**of the following: • MRI Brain without and with contrast (CPT® 70553) • CT Head with contrast (CPT® 70470) • CT Orbits/Maxillofacial with contrast (CPT® 70487)

- PET should not be used unless one of the exceptions stated in section **Neuroblastoma – General Considerations (PEDONC-6.1)** is present.

Background and Supporting Information

- MIBG provides superior sensitivity and sensitivity for detecting viable osseous disease compared with bone scintigraphy so technetium bone scan is not necessary when MIBG is utilized. MIBG is positive in 90% to 95% of neuroblastomas.
  - Most MIBG imaging studies are SPECT/CT studies using CT for localization only. Separate diagnostic CT codes should not be approved for this purpose.
  - Occasionally MIBG cannot be performed prior to initiation of therapy. In this circumstance, MIBG should be completed within 3 weeks of therapy initiation as the reduction in MIBG avidity in response to chemotherapy is not immediate. Inability to complete MIBG before starting therapy is not an indication to approve PET imaging.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Neuroblastoma – Treatment Response Imaging (Risk Group Dependent) (PEDONC-6.4)

ONCP.NP.0006.4.A
v2.0.2026

- Risk Grouping will not be known at the time of initial staging, but is critical for all imaging decisions after initial staging is complete. **The treating oncologist should always know the individual's risk grouping**. It is not possible to establish the appropriate imaging plan for a neuroblastoma individual without knowing his/her risk group.

All Very Low Risk and Low Risk Neuroblastoma Not Receiving Chemotherapy:

Indication	Medically Necessary Imaging Study
All individuals, no sooner than 4 weeks after diagnosis to determine if additional treatment is necessary	• CT with contrast or MRI without and with contrast of the primary tumor site. If primary tumor site is abdomen or pelvis, imaging of both sites is medically necessary. ◦ Ultrasound is medically necessary if requested in place of CT or MRI to avoid radiation and/or anesthesia exposure in low risk individuals

Background and Supporting Information

- Many individuals will be treated with surgical resection only without adjuvant therapy, and these individuals enter immediately into surveillance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

All Intermediate Risk Neuroblastoma and Very Low Risk or Low Risk Neuroblastoma Receiving Chemotherapy:

Indication	Medically Necessary Imaging Study
Prior to surgical resection	• Restaging imaging (MIBG and CT or MRI, as performed at initial diagnosis) • PET/CT or PET/MRI if exceptions noted in **PEDONC-6.1** are met. • Additional imaging for individuals with paraspinal disease: ◦ MRI without and with contrast of the whole spine (CPT® 72156, CPT® 72157, and CPT® 72158)
Treatment response, as often as every 2 cycles of chemotherapy (~every 6 weeks and at the end of planned treatment)	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) OR • MRI Neck (CPT® 70543) without and with contrast, MRI Chest without and with contrast (CPT® 71552), and MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) AND • CT or MRI of other sites with prior measurable disease • Additional imaging for individuals with paraspinal disease: ◦ MRI without and with contrast of the whole spine (CPT® 72156, CPT® 72157, and CPT® 72158)
In addition to treatment response listed above, every 4 cycles, and at the end of planned chemotherapy treatment	• MIBG scan (see table in **Neuroblastoma - General Considerations (PEDONC-6.1)** for MIBG coding details) • 18F-FDG PET/CT or PET/MRI if exceptions noted in **PEDONC-6.1** are met

Background and Supporting Information

- Individuals generally receive 2 to 12 cycles of moderate-intensity chemotherapy depending on response to treatment.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Surgical resection may occur prior to or following chemotherapy depending on disease stage. Restaging prior to surgery is appropriate.

High-Risk Neuroblastoma:

Indication	Medically Necessary Imaging Study
• ANY of the following: ◦ Treatment response ▪ As often as every 2 cycles of chemotherapy, mAb, or biologic therapy (~every 6 weeks) ◦ Change in modality ▪ Prior to surgery, HSCT, XRT, or mAb therapy ◦ End of therapy	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) OR • MRI Neck (CPT® 70543) without and with contrast, MRI Chest without and with contrast (CPT® 71552), and MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) AND • CT or MRI of other sites with prior measurable disease • Additional imaging for individuals with paraspinal disease: ◦ MRI without and with contrast of the whole spine (CPT® 72156, CPT® 72157, and CPT® 72158) • MIBG scan (see table in **Neuroblastoma - General consideration (PEDONC-6.1)** for MIBG coding details)
At completion of ^{131}I-MIBG therapy	• ^{123}I-MIBG scan ◦ FDG-PET cannot be used after ^{131}I-MIBG therapy
Preoperative planning	• More frequent imaging with any of the above modalities can be approved around the time of surgery if needed

Background and Supporting Information

- This group of individuals receives highly aggressive therapy using sequential chemotherapy, surgery, high dose chemotherapy with stem cell rescue, radiotherapy, monoclonal antibody (mAb) immunotherapy, and biologic therapy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Neuroblastoma – Surveillance Imaging (Risk Group Dependent) (PEDONC-6.5)

ONCP.NP.0006.5.A
v2.0.2026

Very Low Risk and Low Risk Neuroblastoma:

Indication	Medically Necessary Imaging Study
All individuals	• At 3, 6, 9, 12, 18, 24, 30 and 36 months after surgery: ◦ Ultrasound of involved areas OR • 3, 6, 9, 12, 18, 24, 30 and 36 months after surgery or to clarify unclear findings on ultrasound: ◦ CT with contrast or MRI without and with contrast of the primary tumor site
Clarification of findings on CT or MRI suspicious for disease recurrence	• MIBG (see table in **Neuroblastoma - General Considerations (PEDONC-6.1)** for MIBG coding details) • 18F-FDG PET/CT or PET/MRI if exceptions noted in **PEDONC-6.1** are met.

Intermediate Risk Neuroblastoma:

Indication	Medically Necessary Imaging Study
All individuals	• Every 3 months for 1 year, then every 6 months for 1 year, and then at 36 months after surgery: ◦ CT with contrast or MRI without and with contrast of the primary tumor ▪ If the primary tumor is paraspinal: - MRI without and with contrast of the whole spine (CPT® 72156, CPT® 72157, and CPT® 72158) ◦ If primary site is abdomen or pelvis, both body sites are medically necessary (CPT® 74177 or the combination of CPT® 71297 and CPT® 74183) ◦ If negative at 36 months, ultrasound at 48 and 60 months after surgery to complete 5 years surveillance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
• BOTH of the following: ◦ Individuals with stage 4, or M disease, or 4S, or MS disease AND ◦ Positive MIBG at completion of therapy	• Until a negative scan is achieved, every 3 months in year 1, then once in year 2 and year 3: ◦ MIBG scan (see table in **Neuroblastoma – General Considerations (PEDONC-6.1)** for MIBG coding details) ◦ Once a negative MIBG is achieved, no further MIBG imaging is necessary. • MIBG is not medically necessary for all other intermediate risk individuals. • 18F-FDG PET/CT or PET/MRI if exceptions noted in **PEDONC-6.1** are met.

High Risk Neuroblastoma:

Indication	Medically Necessary Imaging Study
All individuals	• Every 3 months for 1 year, then every 6 months for 1 year, and then annually to complete 6 years surveillance: ◦ CT with contrast or MRI without and with contrast of the primary tumor site AND ◦ MIBG scan (see table in **Neuroblastoma – General Considerations (PEDONC-6.1)** for MIBG coding details) ▪ 18F-FDG PET/CT or PET/MRI if exceptions noted in **PEDONC-6.1** are met ◦ If primary site is abdomen or pelvis, both body sites are medically necessary (CPT® 74177 or the combination of CPT® 71297 and CPT® 74183) ◦ For history of paraspinal disease, MRI without and with contrast of the whole spine (CPT® 72156, CPT® 72157, and CPT® 72158) ◦ If negative at 6 years, no further advanced imaging.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Suspected recurrence	• CT Chest/Abdomen/Pelvis with contrast (CPT® 71260, and CPT® 74177) or MRI without and with contrast, (CPT® 71552, CPT® 74183, and CPT® 72197) and other sites of prior measurable disease or current symptoms • MRI Brain with and without contrast (CPT® 70553) for signs or symptoms of brain involvement • MRI without and with contrast of the whole spine (CPT® 72156, CPT® 72157, and CPT® 72158) for history of paraspinal disease, back pain, or cord compression symptoms. • MIBG scan (see table in **Neuroblastoma - General Considerations (PEDONC-6.1)** for MIBG coding details) • 18F-FDG PET/CT or PET/MRI if exceptions noted in **PEDONC-6.1** are met.

Background and Supporting Information

- Very Low Risk and Low Risk Neuroblastoma:
  - CT Chest is not indicated in asymptomatic surveillance imaging of any stages of neuroblastoma individuals with no prior history of thoracic disease
- High-Risk Neuroblastoma:
  - Early detection of recurrence with ^{123}I-MIBG has been shown to improve post-relapse outcomes in high-risk neuroblastoma

Pediatric Renal Tumors (PEDONC-7)

Guideline

Pediatric Renal Tumors – General Considerations (PEDONC-7.1)
Unilateral Wilms Tumor (UWT) (PEDONC-7.2)
Bilateral Wilms Tumor (BWT) (PEDONC-7.3)
Pediatric Renal Cell Carcinoma (RCC) (PEDONC-7.4)
Clear Cell Sarcoma of the Kidney (CCSK) (PEDONC-7.5)
Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites (PEDONC-7.6)
Congenital Mesoblastic Nephroma (CMN) (PEDONC-7.7)
References (PEDONC-7)

Pediatric Renal Tumors – General Considerations (PEDONC-7.1)

- Ultrasound is considered first-line imaging for suspected pediatric renal mass, given the lack of radiation exposure and need for sedation. Advanced imaging for suspected Wilms Tumor should be done after initial assessment with ultrasound, which has often been completed prior to diagnosis.
- A variety of tumors can occur in the pediatric kidney, and include the following:
  - Wilms Tumor
    - Favorable Histology (FHWT)
    - Focal Anaplasia (FAWT)
    - Diffuse Anaplasia (DAWT)
    - Bilateral Wilms Tumor (BWT)
  - Renal Cell Carcinoma (RCC)
  - Clear Cell Sarcoma of the Kidney (CCSK)
  - Malignant Rhabdoid Tumor of the Kidney (MRT)
  - Congenital Mesoblastic Nephroma (CMN)
  - Other cancers occurring in the kidney:
    - Neuroblastoma
    - Primitive Neuroectodermal Tumor
    - Rhabdomyosarcoma
    - Non-Rhabdomyosarcoma Soft Tissue Sarcomas
    - These and other rare tumors have been reported occurring primarily in the kidney and should be imaged according to the guidelines for the specific histologic diagnosis.
- For suspected renal tumor, cell type unknown, image according to **Pediatric Renal Cell Carcinoma (RCC) (PEDONC-7.4)**
- PET is not routinely medically necessary for initial staging, treatment response, or surveillance of any pediatric renal tumor - rare circumstances for exceptions are listed in the relevant guideline sections.

Unilateral Wilms Tumor (UWT) (PEDONC-7.2)

ONCP.RC.0007.2.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging	ONE of the following: • MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) OR • CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ Doppler ultrasound to evaluate for tumor thrombus is not medically necessary unless CT findings are inconclusive AND • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ Should be completed prior to anesthesia exposure if possible • PET is not routinely medically necessary in the initial staging of any pediatric renal tumor
Bilateral renal lesions noted on ultrasound or CT	• MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast
Additional initial staging imaging for any individual with neurologic signs or symptoms raising suspicion of CNS metastases	• MRI Brain without and with contrast (CPT® 70553)
Additional initial staging imaging for any individual with signs or symptoms raising suspicion of bony metastases	• Bone scan (see: **PEDONC-1.3** for coding)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	• CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) • CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	• PET/CT (CPT® 78815)
Surveillance	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250), or chest x-ray AND CT Abdomen with contrast (CPT® 74160) or Abdominal US (CPT® 76700) ◦ Every 3 months for 2 years, then every 6 months for 2 additional years, to complete 4 years surveillance • In addition, pelvic imaging (CT or ultrasound) for individuals with stage II or higher disease, for individuals treated with nephrectomy only, or for individuals with a history of tumor rupture, known pelvic involvement, diffuse anaplastic histology, or a history of disease recurrence.
• There are no data to support the use of PET imaging for routine surveillance in any individual with Wilms tumor.	

Background and Supporting Information

- Many individuals will present with an asymptomatic abdominal mass, and will undergo ultrasound as a primary evaluation.
- Only ~0.5% of individuals with Wilms tumor will ever develop brain metastases
- A very low risk subset of stage I FHWT will be observed after nephrectomy, and enter directly into surveillance.
- The majority of individuals will receive chemotherapy with or without XRT, beginning within 14 days of initial surgery.

Bilateral Wilms Tumor (BWT) (PEDONC-7.3)

ONCP.RC.0007.3.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging	ONE of the following: • MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) OR • CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) is often performed prior to discovery of bilateral lesions and should not prevent MRI from being approved if requested ▪ Doppler ultrasound to evaluate for tumor thrombus is not medically necessary unless CT findings are inconclusive AND • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ Should be completed prior to anesthesia exposure if possible • PET is not routinely medically necessary in the initial staging of any pediatric renal tumor
Additional initial staging imaging for any individual with neurologic signs or symptoms raising suspicion of CNS metastases	• MRI Brain without and with contrast (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Additional initial staging imaging for any individual with signs or symptoms raising suspicion of bony metastases	• Bone scan (see: **PEDONC-1.3** for coding)
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	• MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) for individuals with a contraindication to MRI • CT Chest with (CPT® 71260) or without contrast (CPT® 71250)
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	• PET/CT (CPT® 78815)
Surveillance	• Every 3 months for 2 years, then every 6 months for 2 additional years, to complete 4 years surveillance: ◦ CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) or chest x-ray AND ◦ CT Abdomen with contrast (CPT® 74160) or Abdominal US (CPT® 76700) • Pelvic imaging (CT or ultrasound) for individuals with stage II or higher disease, individuals treated with nephrectomy only, or individuals with a history of tumor rupture, diffuse anaplastic histology, known pelvic involvement, or a history of disease recurrence.
• PET is not routinely medically necessary to assess treatment response or for surveillance in Wilms tumor.	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- Many individuals will present with an asymptomatic abdominal mass, and will undergo ultrasound as a primary evaluation.
- Individuals with bilateral Wilms Tumor may begin therapy without a histologic diagnosis to preserve a localized disease stage and attempt to shrink the tumors to allow for renal-sparing surgical approaches.
- Only ~0.5% of Wilms tumor individuals will ever develop brain metastases
- If treating with chemotherapy without a biopsy, disease evaluation is indicated at week 6. If either tumor has not shrunk 50%, then open biopsy is indicated to confirm favorable histology.
- If partial nephrectomy still not feasible at week 6, the next disease evaluation is at week 12. Surgical resection should occur no later than week 12.

Pediatric Renal Cell Carcinoma (RCC) (PEDONC-7.4)

ONCP.RC.0007.4.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ If bilateral renal lesions are noted on ultrasound or CT, MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) should be strongly considered • CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) ◦ Should be completed prior to anesthesia exposure if possible • PET scan is not routinely medically necessary in the initial staging of any pediatric renal tumor
Additional initial staging for any individual with neurologic signs or symptoms raising suspicion of CNS metastases	• MRI Brain without and with contrast (CPT® 70553)
Additional initial staging for any individual with signs or symptoms raising suspicion of bony metastases	• Bone scan (See: **PEDONC-1.3** for coding)
Treatment response in individuals with residual measurable disease after initial surgery and receiving adjuvant medical therapy	• Every 2 cycles during active treatment: ◦ CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) and ◦ CT Abdomen with contrast (CPT® 74160) ▪ Pelvic imaging is not medically necessary unless prior pelvic involvement has been documented

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	• PET/CT (CPT® 78815) • Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**
Surveillance in individuals with documented CNS metastases	• Every 6 months for 2 years after completion of all therapy: ◦ MRI Brain without and with contrast (CPT® 70553)
Surveillance in individuals with TFE3 or TFEB subtype	• Every 3 months for 2 years, then every 6 months for 2 years after completion of all therapy: ◦ CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183) ▪ Pelvic imaging is not medically necessary for surveillance unless prior pelvic involvement has been documented
Surveillance in all other histologies	• See: **Renal Cell Cancer (RCC) – Surveillance (ONC-17.4)**
New signs/symptoms suggestive of CNS recurrence	• MRI Brain without and with contrast (CPT® 70553)
• PET is not routinely utilized to assess treatment response in pediatric RCC.	

Background and Supporting Information

- A majority of pediatric cases have a novel subtype involving TFE3 or TFEB translocations, which have a different natural history than “adult type” RCC
- Individuals of any age with TFE3 or TFEB translocated RCC should be imaged according to this guideline section.
- 40% to 45% of pediatric RCC cases have similar histologies to adult RCC (clear cell, papillary, chromophobe, etc.) and imaging decisions will be similar to general oncology guidelines.
- Individuals with all other subtypes of RCC should be imaged according to **Renal Cell Cancer (RCC) (ONC-17)** in the Oncology Imaging Guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Many individuals will present with an asymptomatic abdominal mass, and will undergo ultrasound as a primary evaluation. Doppler ultrasound to evaluate for tumor thrombus is no longer necessary unless CT findings are inconclusive, and should not be performed if CT is already completed.
- Other staging imaging than what is stated in the above table should be deferred until a histologic diagnosis is made, by complete nephrectomy for most unilateral renal tumors and biopsy for bilateral renal tumors or inoperable unilateral tumors
- Most individuals will have surgical resection of all disease at the time of diagnosis and will enter directly into surveillance

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Clear Cell Sarcoma of the Kidney (CCSK) (PEDONC-7.5)

ONCP.RC.0007.5.A
v2.0.2026

Be careful not to confuse the diagnosis with clear cell RCC. See: Renal Cell Cancer (RCC) (ONC-17) for imaging guidelines.

Indication	Medically Necessary Imaging Study
Initial Staging	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ Doppler ultrasound to evaluate for tumor thrombus is not medically necessary unless CT findings are inconclusive • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ Should be completed prior to anesthesia exposure if possible • Bone scan (see: **PEDONC-1.3** for coding) • MRI Brain without and with contrast (CPT® 70553) • PET is not routinely considered medically necessary in the initial staging of any pediatric renal tumor
Bilateral renal lesions are noted on ultrasound or CT in initial staging	• MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	• CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) • Additionally, for individuals with CNS metastases at initial staging: ◦ MRI Brain without and with contrast (CPT® 70553) Bone scan (see: **Modality General Considerations (PEDONC-1.3)** for coding) at the end of planned therapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	• PET/CT (CPT® 78815) • Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**
Surveillance	• Every 3 months for 2 years after completion of all therapy: ◦ CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) • Every 6 months for 3 years after completion of all therapy: ◦ MRI Brain without and with contrast (CPT® 70553) • Every 3 months for 1 year, then every 6 months for 2 years after completion of all therapy: ◦ Bone scan (see: **Modality General Considerations (PEDONC-1.3)** for coding) ◦ If negative at 36 months, no further advanced imaging. • Other surveillance imaging should be by Abdominal US (CPT® 76700) and chest x-ray

Background and Supporting Information

- Many individuals will present with an asymptomatic abdominal mass, and will undergo ultrasound as a primary evaluation.
- Other staging imaging should be deferred until a histologic diagnosis is made, by complete nephrectomy for most unilateral renal tumors and biopsy for bilateral renal tumors or inoperable unilateral tumors

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Malignant Rhabdoid Tumor of the Kidney (MRT) and Other Extracranial Sites (PEDONC-7.6)

ONCP.RC.0007.6.A
v2.0.2026

Be careful not to confuse the diagnosis with rhabdomyosarcoma. See: **Rhabdomyosarcoma (RMS) (PEDONC-8.2)** for Imaging Guidelines

Indication	Medically Necessary Imaging Study
Initial Staging	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ Doppler ultrasound to evaluate for tumor thrombus is not medically necessary unless CT findings are inconclusive • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ Should be completed prior to anesthesia exposure if possible • Bone scan (see: **PEDONC-1.3** for coding) • MRI Brain without and with contrast (CPT® 70553) • PET is not routinely medically necessary in the initial staging of any pediatric renal tumor
Bilateral renal lesions are noted on ultrasound or CT in initial staging	• MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	• CT Chest with (CPT® 71260) *or* CT Chest without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) ◦ If primary site other than kidney, perform CT with contrast or MRI without and with contrast of primary site in place of abdominal and pelvic imaging • MRI Brain without and with contrast (CPT® 70553): ◦ Every 2 cycles during treatment for individuals with CNS metastases at initial staging ◦ At the end of planned therapy for all individuals • Bone scan (see: **PEDONC-1.3** for coding) at the end of planned therapy only if positive at initial diagnosis
Rare circumstances to establish the presence of active disease only when a major therapeutic decision depends on PET avidity	• PET/CT (CPT® 78815) • Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	• Every 3 months for 2 years after completion of all therapy: ◦ CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) • Every 3 months for 3 years after completion of all therapy: ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) ▪ If primary site other than kidney, perform CT with contrast or MRI without and with contrast of primary site in place of abdominal imaging • Every 3 months for 1 year, then every 6 months for 1 year after completion of all therapy: ◦ MRI Brain without and with contrast (CPT® 70553) • If bone scan positive at initial diagnosis: ◦ Every 3 months for 1 year, then every 6 months for 2 years: ▪ Bone scan (see: **PEDONC-1.3** for coding) ◦ If negative at 36 months, no further advanced imaging • The role of surveillance imaging beyond these timeframes in unclear. Abdominal US (CPT® 76700) and chest x-ray may be considered.
Continued surveillance of individuals with rhabdoid tumor predisposition syndrome	• See: **Rhabdoid Tumor Predisposition Syndrome (PEDONC-2.11)**

Background and Supporting Information

- MRT is a highly aggressive histologic variant that can also occur in other locations and all non-CNS sites should follow these guidelines.
- Primary CNS rhabdoid malignancies should be imaged according to **Atypical Teratoid/Rhabdoid Tumors (ATRT) PEDONC-4.5)**
- Many individuals will present with an asymptomatic abdominal mass, and will undergo ultrasound as a primary evaluation.
- Other staging imaging should be deferred until a histologic diagnosis is made, by complete nephrectomy for most unilateral renal tumors and biopsy for bilateral renal tumors or inoperable unilateral tumors

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Congenital Mesoblastic Nephroma (CMN) (PEDONC-7.7)

ONCP.RC.0007.7.A
v2.0.2026

Congenital Mesoblastic Nephroma Initial Staging

- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary in all individuals
- CT Chest with (CPT® 71260) is medically necessary to evaluate inconclusive findings on chest x-ray

Congenital Mesoblastic Nephroma Treatment Response

- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary once following resection to establish baseline imaging, and those with a complete resection should then be imaged according to surveillance guidelines
- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for individuals receiving preoperative chemotherapy every 2 cycles of therapy until surgery and then should be imaged according to surveillance guidelines after their postoperative baseline imaging study

Congenital Mesoblastic Nephroma Surveillance Imaging

- Ultrasound is medically necessary as it is the preferred surveillance imaging modality to avoid radiation and anesthesia exposures
- CT Abdomen and Pelvis with contrast (CPT® 74177) **or** MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary for residual abnormalities present on post-operative imaging or inconclusive findings on ultrasound every 3 months for 1 year after completion of all therapy

Background and Supporting Information

- This is the most common primary renal tumor occurring in young infants, and the overall prognosis is very good
- Complete surgical removal is curative in most cases, and histologically confirmed metastatic disease or bilateral disease has never been reported
- Many individuals will present with an asymptomatic abdominal mass at the time of birth or abnormal prenatal ultrasound, and will undergo ultrasound as a primary evaluation.
- PET is not indicated in the initial staging of any pediatric renal tumor
- Recurrences are rare but most occur within 12 months of diagnosis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Pediatric Soft Tissue Sarcomas – General Considerations (PEDONC-8.1)

ONCP.SS.0008.1.A

v2.0.2026

- Unless specified below, individuals age <18 years old should be imaged according to this guideline section. Exceptions include:
  - Rhabdomyosarcoma in individuals (except uterine rhabdomyosarcoma) of all ages should be imaged according to guidelines in **Rhabdomyosarcoma (RMS) (PEDONC-8.2)**
  - Uterine rhabdomyosarcoma individuals of all ages should be imaged according to guidelines in Uterine Cancer (ONC-22). See: **Uterine Cancer - General Considerations (ONC-22.0)** in the Oncology Imaging Guidelines
  - Kaposi's sarcoma in individuals of all ages should be imaged according to guidelines in **Kaposi's Sarcoma (ONC-31.10)** in the Oncology Imaging Guidelines
- Evaluation of soft tissue masses of uncertain nature prior to biopsy should follow general imaging guidelines:
  - Individuals age 0 to 17 years, see: **Soft Tissue and Bone Masses (PEDMS-3)** in the Pediatric Musculoskeletal Imaging Guidelines
  - Individuals age ≥18 years, see: **Bone Lesion (MS-10.2)** in the Musculoskeletal Imaging Guidelines
- Where there are indications for PET/CT in these guidelines, note that indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**

Rhabdomyosarcoma (RMS) (PEDONC-8.2)

ONCP.SS.0008.2.A

v2.0.2026

- Individuals of all ages are imaged according to this guideline, with exception of uterine rhabdomyosarcoma, which is imaged according to Uterine Cancer (ONC-22). See: **Uterine Cancer – General Considerations (ONC-22.0)** in the Oncology Imaging Guidelines.

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	ALL of the following: • MRI without and with contrast of primary site ◦ CT with contrast if MRI is contraindicated • CT Chest with contrast or CT Chest without contrast ◦ should be completed prior to anesthesia exposure if possible • Whole-Body PET/CT (CPT® 78816) ◦ Bone scan substituted for PET, if PET not available
Additional initial staging for ANY of the following: • evaluation of inconclusive PET findings in the abdomen or pelvis • primary site of abdomen or pelvis • lower extremity primary site	• CT Abdomen and Pelvis with contrast (CPT 74177)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Additional initial staging for ANY of the following: • Primary site involving the paraspinal or paravertebral region • PET or bone scan-avid lesions in skull, neck, vertebrae • Neurologic signs or symptoms raising suspicion of CNS metastases	ALL of the following: • MRI Brain (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)
Treatment response, every 2 cycles during treatment, prior to local control surgery, and at the end of planned therapy	ALL of the following: • CT Chest with (CPT® 71260) contrast or CT Chest without contrast (CPT® 71250) • MRI without and with contrast of primary site ◦ CT if used at initial imaging for MRI contraindication • CT with contrast or MRI without and with contrast of all known metastatic sites using the same conventional imaging modality as per initial staging
ANY of the following: • Response assessment prior to local control surgery or radiation therapy • Evaluation of residual mass visible on conventional imaging as part of end of therapy evaluation • Response assessment of disease visible on PET but not conventional imaging • PET results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.	• Whole-body PET/CT (CPT® 78816) ◦ Once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET is not medically necessary for continued disease monitoring or surveillance unless one of the exceptions in section **General Guidelines (PEDONC-1.0)** applies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Restaging following local control surgery	ALL of the following: • MRI without and with contrast of primary site ◦ CT if used at initial imaging for MRI contraindication • CT with contrast or MRI without and with contrast of all known metastatic sites using the same conventional imaging modality as per initial staging
Surveillance, localized RMS	ALL of the following, every 3 months for 1 year, then every 4 months for 2 years, then every 6 months for 1 year after completion of all therapy; and for patients diagnosed at age 18 or older, annually indefinitely: • MRI without or without and with contrast of primary tumor site ◦ CT if MRI contraindicated • Chest x-ray ◦ CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) for new or worsening clinical symptoms of chest disease or new findings on chest x-ray
Surveillance, metastatic RMS	ALL of the following, every 3 months for 1 year, then every 4 months for 2 years, then every 6 months for 1 year after completion of all therapy;and for patients diagnosed at age 18 or older, annually indefinitely: • MRI without or without and with contrast of primary tumor site • CT if contraindication to MRI • CT Chest with (CPT® 71260) *or* without contrast (CPT® 71250) • CT with or without contrast of all known metastatic sites • Nuclear bone scan (see: **PEDONC-1.3** for coding) for surveillance of known bony metastases

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected recurrence	• Repeat conventional imaging as per initial staging for all individuals
ONE of the following: • Biopsy-proven recurrence • Conventional imaging (CT, MRI, US, plain film) reveals findings that are inconclusive or suspicious for recurrence, and PET avidity will determine whether biopsy or continued observation is appropriate • Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence, and PET would replace conventional imaging modalities.	• Whole-body PET/CT (CPT® 78816)

Background and Supporting Information

- Soft tissue sarcomas occur in both adult and pediatric individuals, but some are more common in one age group than the other.
- Pediatric soft tissue sarcomas are divided into **two** groups:
  - Rhabdomyosarcoma (RMS) accounts for ~60% of soft tissue sarcomas in young individuals, but only ~25% of soft tissue sarcomas in adolescents.
  - Non-rhabdomyosarcoma soft tissue sarcomas (NRSTS) which encompasses all other histologic subtypes.
- Because RMS can arise from any muscle tissue, the presenting symptoms and primary tumor sites vary widely and strongly influence the appropriate imaging decisions.
- CT with contrast is the preferred primary site imaging modality for RMS arising in the thoracic cavity (not the chest wall).
- MRI without and with contrast is the preferred primary site imaging modality for RMS occurring in all other anatomic locations, including the chest wall.
- PET/CT is superior to conventional imaging for detection of nodal and bony metastases in pediatric RMS and is indicated in the initial staging of all individuals after histologic diagnosis is established.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely indicated in the initial metastatic staging of pediatric RMS.
- PET is not routinely utilized to assess treatment response in RMS.
- PET is generally not indicated during active treatment for recurrent pediatric cancer.
- Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging during surveillance.
- PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance.

Non-Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS) (PEDONC-8.3)

ONCP.SS.0008.3.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial staging of all individuals	ALL of the following: • MRI without and with contrast of primary site ◦ CT with contrast if contraindication to MRI • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) ◦ Should be completed prior to anesthesia if possible • For primary tumor of the chest wall, both MRI Chest wall without and with contrast (CPT® 71552) and CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) to assess for pulmonary metastatic disease (indicated simultaneously) • PET/CT (CPT® 78815) ◦ Whole-body PET/CT (CPT® 78816) if there is clinical suspicion of skull or distal lower extremity involvement • Nuclear bone scan (see: **PEDONC-1.3** for coding) if PET is not available

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
ANY of the following: • Additional initial staging for individuals with disease in the abdomen, pelvis, or lower extremities • Angiosarcoma, alveolar soft part sarcoma, clear cell sarcoma, epithelioid sarcoma, hemangiopericytoma, leiomyosarcoma, liposarcoma, retroperitoneal or intra-abdominal primary site (including pelvic primary site), other histologies documented to have propensity for lymphatic spread and deep-seated tumors • Inconclusive findings in the abdomen or pelvis on PET/CT	In addition to the above, one of the following combinations: • CT Abdomen and Pelvis with contrast (CPT® 74177) if not already performed • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • MRI Abdomen (CPT® 74183) with and without contrast and CT Pelvis (CPT® 72193) with contrast • CT Abdomen (CPT® 74160) with contrast and MRI Pelvis (CPT® 72197) without and with contrast
Further evaluation of ANY of the following: • PET or nuclear bone scan-avid lesions in skull, neck, or vertebrae seen on initial imaging • Neurologic signs or symptoms raising suspicion of CNS metastases • Myxoid round cell liposarcoma, angiosarcoma, alveolar soft part sarcoma, cardiac sarcoma • Additional staging for individuals with primary site arising in the paraspinal or paravertebral region	ALL of the following: • MRI Brain (CPT® 70553) • MRI Spine (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Treatment response, every 2 cycles of treatment, prior to local control, and at the end of planned therapy	Either of the following: • CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250), and • MRI without and with contrast of primary site ◦ CT if contraindication to MRI and • CT Abdomen and Pelvis with contrast (CPT® 74177) for the same indications as abdominal/ pelvic imaging for initial staging • Imaging of all known metastatic sites using the same conventional imaging modality as per initial staging OR • PET/CT (CPT® 78815) if disease visible on initial staging PET but not on conventional imaging ◦ Whole-body PET/CT (CPT® 78816) if there is clinical suspicion of skull or distal lower extremity involvement
ANY of the following, if PET positive at initial diagnosis: • Assessment prior to local control surgery or radiation therapy • Evaluation of residual mass visible on conventional imaging as part of end of therapy evaluation • Rare circumstances when PET results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance	• PET/CT (CPT® 78815) ◦ Whole-body PET/CT (CPT® 78816) if there is clinical suspicion of skull or distal lower extremity involvement ◦ Once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET is not medically necessary for continued disease monitoring or surveillance unless one of the exceptions in section **General Guidelines (PEDONC-1.0)** applies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Restaging following local control surgery	ALL of the following: • MRI without and with contrast of the primary site ◦ CT if contraindication to MRI • Imaging of all known metastatic sites using the same conventional imaging modality as per initial staging • CT Abdomen and Pelvis with contrast (CPT® 74177) for the same indications as abdominal/ pelvic imaging for initial staging
Surveillance, low grade, localized NRSTS of extremity or trunk treated with resection (with or without radiation) or chemotherapy	Every 3 months for the first 12 months, then every 4 months in years 2 and 3, and every 6 months in years 4 and 5, then annually thereafter: • MRI without and with contrast of the primary site • CT if MRI contraindicated AND Every 6 months for 3 years, then annually thereafter: • CT Abdomen and Pelvis with contrast (CPT® 74177) for the same indications as abdominal/ pelvic imaging for initial staging • CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250)
Surveillance all other NRSTS	Every 3 months for the first 2 years, then every 6 months in years 3 and 4, and then annually: • MRI without and with contrast of the primary site ◦ CT if MRI contraindicated ◦ Nuclear bone scan (see: **PEDONC-1.3** for coding) for surveillance of known bony metastases • CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) for the same indications as abdominal/ pelvic imaging for initial staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
ANY of the following: • Angiosarcoma • Alveolar soft part sarcoma • Cardiac sarcoma	• In addition to the above studies: ◦ MRI Brain without and with contrast (CPT® 70553) annually For surveillance of individuals with known brain metastases, see: **Brain Metastases (ONC-31.3)**
Surveillance, recurrent NRSTS	ALL of the following after successful treatment for recurrent disease, every 3 months for 1 year (surveillance after year 1 should follow the standard timing listed in the appropriate surveillance section above): • CT Chest (CPT® 71260) with contrast • CT with contrast or MRI without and with contrast of the primary site • CT Abdomen and Pelvis with contrast (CPT® 74177) for the same indications as abdominal/ pelvic imaging for initial staging
ANY of the following: • Conventional imaging (CT, MRI, US, plain film) during surveillance reveals findings that are inconclusive or suspicious for recurrence, and PET avidity will determine whether biopsy or continued observation is appropriate • Obvious clinical symptoms show strong evidence suggesting recurrent and PET would replace conventional imaging modalities	• PET/CT (CPT® 78815) ◦ Whole-body PET/CT (CPT® 78816) if there is clinical suspicion of skull or distal lower extremity involvement

Background and Supporting Information

- All soft tissue sarcomas other than RMS fall into this category
- Because soft tissue sarcomas can arise from any soft tissue, the presenting symptoms and primary tumor sites vary widely and strongly influence the appropriate imaging decisions

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely indicated in the initial metastatic staging of pediatric NRSTS
- Many individuals with NRSTS will be treated with surgical resection alone, and these individuals enter immediately into surveillance
- PET imaging is not routinely utilized to assess treatment response in NRSTS
- PET imaging is generally not indicated during active treatment for recurrent pediatric cancer.
- Residual mass that has not changed in size since the last conventional imaging does not justify PET
- PET avidity in a residual mass at the end of planned therapy is not an indication for PET imaging during surveillance
- Given that pediatric-specific resources are limited in regards to surveillance of NRSTS, this guideline combines published pediatric literature with NCCN recommendations for the same histologies.

Bone Tumors – General Considerations (PEDONC-9.1)

ONCP.BT.0009.1.A
v2.0.2026

These guidelines include both benign and malignant lesions.

- Unless specified below, individuals who are <18 years old should be imaged according to this guideline section. Exceptions include:
  - Osteogenic sarcoma individuals of all ages should be imaged according to guidelines in **Osteogenic Sarcoma (OS) (PEDONC-9.3)**.
  - Ewing Sarcoma and Primitive Neuroectodermal Tumor individuals of all ages should be imaged according to guidelines in **Ewing Sarcoma and Primitive Neuroectodermal Tumors (ESFT) (PEDONC-9.4)**.
  - Chondrosarcoma individuals of all ages should be imaged according to guidelines in **Bone Sarcomas – Initial Work-up/Staging (ONC-12.6)**.
  - Chordoma individuals of all ages should be imaged according to guidelines in **Bone Sarcomas – Initial Work-up/Staging (ONC-12.6)**.
  - Giant cell tumor of bone and enchondroma individuals of all ages should be imaged according to guidelines in **Benign Bone Tumors – General Considerations (ONC-12.9)**.
  - Other benign bone tumors in pediatric individuals should be imaged according to guidelines in **Benign Bone Tumors (PEDONC-9.2)**.
- Prosthetic devices for children after surgery for bony tumors are nearly all customized.
  - CT, contrast as requested in alignment with prosthetic manufacturer specifications, is medically necessary when requested by the operating surgeon for planning for customized-to-individual joint replacement or prosthetic surgery.
- All bone tumors should be evaluated by plain x-ray prior to any advanced imaging.
- PET does not reliably distinguish between benign and malignant bone tumors and should not be performed prior to biopsy.
- Where indications for PET/CT are noted, please note that indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**.
- CT Chest is superior to PET/CT for the detection of pulmonary metastases, and is medically necessary in the initial workup of all suspected malignant bone tumors.
  - CT Chest should be completed prior to anesthesia exposure, if possible.

Benign Bone Tumors (PEDONC-9.2)

ONCP.BT.0009.2.A
v2.0.2026

- Osteochondroma

Indication	Medically Necessary Imaging Study
Preoperative planning	• MRI without and with contrast after evaluation by the operating surgeon • See: **General Considerations (PEDONC-9.1)** for requests related to prosthetic planning
• ANY of the following: ◦ Concern for malignant transformation ◦ New or worsening pain/symptoms ◦ Change on a recent plain x-ray	• MRI without contrast or without and with contrast

- Osteoid osteoma

Indication	Medically Necessary Imaging Study
Suspected, based on clinical history and plain film findings	• CT without contrast
• ANY of the following: ◦ CTs are not characteristic for diagnosis ◦ Individual has bone pain not localized to the area of findings on CT or x-ray	• ONE of the following: ◦ Triple phase bone scan (CPT® 78315) ◦ SPECT (CPT® 78803) ◦ Hybrid SPECT/CT (CPT® 78830)
• Individuals with new pain who have been previously treated with radiofrequency ablation or curettage	• Bone scan (CPT® code 78830, 78315, or 78803 – as requested)

- Other benign tumors
  - Refer to **Mass Involving Bone (Including suspected Lytic and Blastic Metastatic Disease) (PEDMS-3.4)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- Plain x-ray appearance is diagnostic for many benign bone tumors, and advanced imaging is generally unnecessary except for preoperative planning
- Plain x-ray appearance is diagnostic for osteochondroma for the majority of individuals and advanced imaging is generally unnecessary

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Osteogenic Sarcoma (OS) (PEDONC-9.3)

ONCP.BT.0009.3.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Suspected or Biopsy Proven Diagnosis	• MRI without and with contrast of the primary site OR • CT, contrast as request, of the primary site if there is a contraindication to MRI AND • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Chest is medically necessary in initial workup of all suspected malignant bone tumors in children and should be completed prior to anesthesia exposure if possible • These studies are medically necessary even when PET/CT has already been authorized or performed
Initial Staging of Biopsy Proven Disease	• 18F-FDG PET/CT whole-body (CPT® 78816) ◦ Nuclear bone scan (see: **(PEDONC-1.3)** for coding) if PET not available ◦ PET/CT is medically necessary in addition to the conventional imaging listed in the suspected/ diagnosis sections • CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely medically necessary in the initial metastatic staging of pediatric OS but is medically necessary in the following situations: ◦ Evaluation of inconclusive PET findings ◦ Primary site of abdomen or pelvis
Suspected bony metastatic sites noted on PET or bone scan	• MRI without and with contrast of the suspected metastatic site OR • CT with contrast of the suspected metastatic site

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Restaging after 10 to 12 weeks of neoadjuvant chemotherapy prior to local control surgery	• MRI without and with contrast of primary site • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) • 18F-FDG PET/CT whole-body (CPT® 78816) or bone scan (see: **(PEDONC-1.3)** for coding)
Individuals with metastatic disease undergoing current chemotherapy	• CT Chest with (CPT®) or without contrast (CPT® 71250) can be performed every 2 cycles during treatment and at the end of planned chemotherapy • MRI without and with contrast of primary site can be performed every 2 cycles during treatment and at the end of planned chemotherapy • If previously positive for bony metastases, 18F-FDG PET/CT whole body (CPT® 78816) or bone scan (see: **(PEDONC-1.3)** for coding) every 2 cycles during treatment and at the end of planned chemotherapy • Imaging may be indicated more frequently around the time of surgical resection of primary or metastatic lesions to assess for resectability
Preoperative planning for local control surgery	• CT, contrast as requested • MRA and/or CTA may rarely be indicated for complicated surgical resections, and is medically necessary after evaluation by the operating surgeon to clarify inconclusive MRI findings for preoperative planning • See: **General Considerations (PEDONC-9.1)** for advancing imaging requests related to prosthetic planning

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Following local control surgery, until the end of planned adjuvant chemotherapy	• MRI without and with contrast of primary site ~6 weeks after surgical procedure, and at the end of planned chemotherapy • Plain x-rays of the primary site and chest immediately after local control and then every 2 months between the supported, listed advanced imaging studies. • CT Chest with (CPT® 71260) or without contrast (CPT® 71250): ◦ Measurable pulmonary metastases: every 6 weeks, and at the end of planned chemotherapy ◦ No measurable pulmonary metastases: every 4 months, and at the end of planned chemotherapy • Bone scan (see: **(PEDONC-1.3)** for coding) every 4 months, and at the end of planned chemotherapy ◦ 18F-FDG PET/CT whole-body (CPT® 78816) in place of bone scan, if positive for distant bone metastases at initial diagnosis
Recurrent metastatic or recurrent unresectable disease on treatment	• The following every 2 cycles of treatment, and at the end of planned chemotherapy: ◦ CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ MRI without and with contrast of primary site ◦ PET is generally not medically necessary during active treatment for recurrent pediatric cancer. In rare circumstances, 18F-FDG PET/CT imaging with CPT® 78816 may be appropriate when results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance (all individuals regardless of primary site)	• Any or all of the following every 3 months for year 1 and 2, then every 4 months in year 3, then every 6 months in year 4 and 5 after completion of all therapy ◦ CT or MRI of primary site as performed during suspected or initial disease workup (provided the individual does not have an endoprosthesis that will cause MRI or CT artifact): ▪ CT Chest with (CPT® 71260) or without contrast (CPT® 71250) • Bone scan (see: **(PEDONC-1.3)** for coding) every 3 months for 1 year, then every 4 months for 1 year, then every 6 months for 1 year, then annually for 2 years after completion of all therapy
Suspected recurrence	• MRI without and with contrast of the primary site and / or site of suspected recurrence based on symptoms or other imaging OR • CT, contrast as request, of the primary site and/or site of suspected recurrence based on symptoms or other imaging if there is a contraindication to MRI AND • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Chest is medically necessary in initial workup of all suspected malignant bone tumors in children and should be completed prior to anesthesia exposure if possible • CT Abdomen and Pelvis with contrast (CPT® 74177) is not routinely medically necessary in the metastatic staging of pediatric OS, but is medically necessary in the following situations: ◦ Evaluation of inconclusive PET findings ◦ Primary site of abdomen or pelvis • These studies are medically necessary even when PET/CT has already been authorized or performed

Proprietary Information of UnitedHealthcare.

Indication	Medically Necessary Imaging Study
• For suspected recurrence, ANY of the following: ◦ Conventional imaging reveals findings that are inconclusive or suspicious for recurrence and PET avidity will determine whether biopsy or continued observation is appropriate ◦ Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities	• 18F-FDG PET/CT (CPT® 78816)
• Biopsy-proven recurrence	• PET/CT whole-body (CPT® 78816) for biopsy-proven recurrence ◦ If disease is considered potentially resectable, follow osteosarcoma treatment response as previous

Ewing Sarcoma Family of Tumors (ESFT), Including Primitive Neuroectodermal Tumors (PNET) (PEDONC-9.4)

ONCP.BT.0009.4.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Suspected/Diagnosis – ill-defined or non-discrete soft tissue mass without bony involvement	• US (CPT® 76881 or 76882) in addition to plain x-ray
Suspected or Biopsy Proven Diagnosis – Primary site	• MRI without and with contrast ◦ CT, contrast as requested, if there is a contraindication to MRI • MRA and/or CTA may rarely be indicated for complicated surgical resections, and is medically necessary after evaluation by the operating surgeon to clarify inconclusive MRI findings for preoperative planning • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Chest is medically necessary in initial workup of all suspected or confirmed malignant bone tumors in children and should be completed prior to anesthesia exposure if possible • These studies are medically necessary even when PET/CT has already been authorized or performed

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Suspected or Biopsy Proven Diagnosis – Chest wall primary	• MRI Chest without and with contrast AND • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Chest is medically necessary in initial workup of all suspected or confirmed malignant bone tumors in children and should be completed prior to anesthesia exposure if possible • These studies are medically necessary even when PET/CT has already been authorized or performed
Initial Staging (additional imaging after biopsy confirmed disease)	• PET/CT whole-body (CPT® 78816) ◦ Bone scan (see **(PEDONC-1.3)** for coding) substituted for PET imaging if PET not available ◦ PET/CT is medically necessary in addition to the conventional imaging listed in the suspected/ diagnosis sections
• For ANY of the following: ◦ Evaluation of inconclusive PET findings ◦ Primary site involving the abdomen or pelvis	• CT Abdomen and Pelvis with contrast (CPT® 74177)
Restaging after 10 to 12 weeks of neoadjuvant chemotherapy prior to local control surgery	Imaging modality should be the same as used for initial staging, any or all from the list below as described: • MRI without and with contrast of the primary site • CT (contrast as requested) if requested per valuation by the operating surgeon for pre-operative planning ◦ See **General Considerations (PEDONC-9.1)** for imaging requests related to prosthetic planning. • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) • ONE of the following: ◦ PET/CT whole-body (CPT® 78816) ◦ Whole-body bone scan (see **PEDONC-1.3** for coding) ◦ MRI bone marrow blood supply/diffusion-weighted MRI with ADC (CPT® 77084)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Treatment response following local control surgery	• MRI without and with contrast of primary site 3 months after surgical procedure and at the end of planned chemotherapy • Plain x-rays of the primary site and chest immediately after local control then every 3 months • CT Chest with (CPT® 71260) or without contrast (CPT® 71250): ◦ Measurable pulmonary metastases: every 6 weeks and at the end of planned chemotherapy ◦ No measurable pulmonary metastases: every 3 months and at the end of planned chemotherapy • Whole-body bone scan (see **PEDONC-1.3** for coding) at the end of planned chemotherapy • PET/CT whole-body (CPT® 78816) for clinical or imaging findings suggestive of local recurrence
Individuals with metastatic disease undergoing current chemotherapy	• CT Chest with (CPT® 71260) or without contrast (CPT® 71250) every 2 cycles during treatment and at the end of planned chemotherapy • MRI without and with contrast of primary site every 2 cycles during treatment and at the end of planned chemotherapy • If previously positive for bony metastases, PET/CT whole-body (CPT® 78816) or bone scan (see **[PEDONC-1.3]** for coding) every 2 cycles during treatment and at the end of planned chemotherapy • Imaging may be indicated more frequently around the time of surgical resection of primary or metastatic lesions to assess for resectability • CT with contrast of other sites of involvement

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Recurrent metastatic or recurrent unresectable disease on treatment	• Every 2 cycles of treatment, and at the end of planned chemotherapy: ◦ CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ MRI without and with contrast of primary site ◦ PET imaging is medically necessary when results are likely to result in a treatment change for the individual, including a change from active treatment to surveillance.
Surveillance for all disease **other than** low grade, stage I disease	• Every 3 months for year 1 and 2, then every 4 months in year 3, then every 6 months in year 4 and 5, and annually for 5 years after completion of all therapy to complete 10 years of surveillance: ◦ CT or MRI of primary site as performed during suspected or initial disease workup (provided the individual does not have an endoprosthesis that will cause MRI or CT artifact): ◦ Bone scan (see **(PEDONC-1.3)** for coding) • Every 3 months for year 1 and 2, then every 4 months in year 3, then every 6 months in year 4 and 5: ◦ CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ After year 5, CXR should be used for surveillance

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Surveillance for low grade stage I disease only	• Every 3 months for year 1 and 2, then every 4 months in year 3, then every 6 months in year 4 and 5, and annually for 5 years after completion of all therapy to complete 10 years of surveillance: ◦ CT or MRI of primary site as performed during suspected or initial disease workup (provided the individual does not have an endoprosthesis that will cause MRI or CT artifact) ◦ Bone scan (see **PEDONC-1.3** for coding) • Every 3 months for year 1 and 2 ◦ CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ After 24 months off therapy, CXR should be used for surveillance with CT supported for new or inconclusive findings on CXR
Suspected Recurrence	• MRI without and with contrast of the primary site and/or site of suspected recurrence based on symptoms or other imaging, OR • CT, contrast as request, of the primary site and/or site of suspected recurrence based on symptoms or other imaging if there is a contraindication to MRI AND • CT Chest with (CPT® 71260) or without contrast (CPT® 71250) ◦ CT Chest is medically necessary in initial workup of all suspected malignant bone tumors in children and should be completed prior to anesthesia exposure if possible • CT Abdomen and Pelvis with contrast (CPT® 74177) is not medically necessary in the metastatic staging of pediatric EWS but is medically necessary in the following situations only: ◦ Evaluation of inconclusive PET findings ◦ Primary site of abdomen or pelvis • The studies above are medically necessary even when PET/CT has already been authorized or performed

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• For suspected recurrence, any of the following: ◦ Conventional imaging reveals findings that are inconclusive or suspicious for recurrence and PET avidity will determine whether biopsy or continued observation is appropriate ◦ Rare circumstances where obvious clinical symptoms show strong evidence suggesting recurrence and PET would replace conventional imaging modalities	PET/CT whole-body (CPT® 78816)
• Biopsy proven recurrence	• Refer to ESFT initial imaging for studies for suspected recurrence. • PET/CT whole-body (CPT® 78816) • If disease is considered potentially resectable, follow ESFT treatment response as previously noted

Background and Supporting Information

- Bone and bone marrow metastases can occur in ESFT, and cause a significant change in treatment approach.
- 18F-FDG PET/CT can replace bone scan and bone marrow biopsy in ESFT individuals and is indicated in the initial staging of all ESFT individuals after histologic diagnosis is established.

Pediatric Germ Cell Tumors (PEDONC-10)

ONCP.GC.0010.A
v2.0.2026

Indication	Medically Necessary Imaging Study
Initial staging for all individuals	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ For testicular masses, MRI Abdomen without and with contrast (CPT® 74183) and CT Pelvis with contrast (CPT® 72193) are medically necessary instead, if requested • CT Chest with contrast (CPT® 71260) ◦ Should be completed prior to anesthesia exposure if possible
• Initial staging, in lieu of CT Abdomen and Pelvis with contrast (above), for ANY of the following: ◦ Proven or highly suspected ovarian neoplasm that was already imaged with ultrasound ◦ Immature sacrococcygeal teratoma suspected on other imaging ◦ Contraindication to CT contrast OR • To clarify inconclusive findings on initial staging CT	• MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
• Ovarian masses that are <10 cm in size, have minimal or no visible solid component on ultrasound, and have normal tumor markers	• These are almost universally benign teratomas or functional cysts; thus, advanced imaging is not medically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• Additional initial evaluation for individuals with ANY of the following: ◦ Symptoms suggesting CNS metastases ◦ Choriocarcinoma syndrome (hemorrhagic metastatic disease to lung with extremely elevated HCG) HCG >10,000miU/ml	• MRI Brain without and with contrast (CPT® 70553)
Additional initial evaluation for individuals with systemic symptoms or bone pain	• Nuclear bone scan (See: **PEDONC-1.3** for coding)
Restaging in individuals with disease not completely resected at initial diagnosis	• Every 2 cycles (~every 6 weeks) and at the end of planned therapy: ◦ CT Chest/Abdomen/Pelvis (CPT® 71260 and CPT® 74177) with contrast ▪ CT imaging may be indicated more frequently to assess for surgical resectability in individuals who have received more than 4 cycles of chemotherapy ▪ MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) in lieu of CT abdomen and pelvis for ovarian neoplasms if this modality was used for initial staging or for contraindication to CT contrast ◦ Imaging of any metastatic sites with the same modality used during initial staging
• Suspicious lesion seen on CT and both of the following: ◦ Relapse risk is determined to be low by the treating physician ◦ Biopsy would cause unnecessary morbidity for the individual	• Short-interval CT study of the involved area

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Stage I individuals age 0-10 years treated with surgery only	• Chest x-ray should be completed every 3 months for 1 year, then every 6 months in year two, to complete two years surveillance after completion of all therapy ◦ For those with primary mediastinal tumors at diagnosis, CT Chest with contrast (CPT® 71260) in lieu of CXR according to the above schedule. • Every 3 months for 1 year, then every 6 months in year two, to complete two years surveillance after completion of all therapy: ◦ CT Abdomen/Pelvis with contrast (CPT® 74177) ▪ MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) substituted for surveillance for ovarian neoplasm if this modality was used for initial staging
Stage I individuals ages 11+ years treated with surgery only	• Every 4 months for 2 years, then every 6 months for 1 year, then every 12 months for 2 years to complete 5 years surveillance imaging after completion of all therapy: ◦ Chest x-ray ◦ For individuals with primary mediastinal tumors at diagnosis, CT Chest with contrast (CPT® 71260) in lieu of chest x-ray on the above schedule. • Every 4 months for 2 years, then every 6 months for 1 year, then every 12 months for two years to complete 5 years surveillance ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) ▪ MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) substituted for surveillance for ovarian neoplasm if this modality was used for initial staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Stage II-IV individuals	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) and CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for 1 year then every 6 months in year 2, then annually in years 3-5 after completion of all therapy. ◦ MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) substituted for surveillance for ovarian neoplasm if this modality was used for initial staging • Individuals with brain or bone metastases should have surveillance imaging of those areas on the same schedule as the primary site imaging with the same modality used during initial staging
• Suspected Recurrence: ◦ Any clinically significant rise in tumor markers ◦ Symptoms suggesting recurrent disease ◦ Abnormal chest x-ray	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) in lieu of CT for suspected recurrence of immature sacrococcygeal tumor or ovarian neoplasm or for contraindication to CT contrast • Whole-body bone scan (CPT® 78306) for individuals with a history of bone involvement or with bone pain
Clarify inconclusive findings on conventional imaging	PET/CT (CPT® 78815)

Background and Supporting Information

General Considerations:

- Malignant pediatric germ cell tumors commonly include one of four histologic subtypes:
  - Yolk sac tumor
  - Choriocarcinoma
  - Embryonal carcinoma
  - Mixed histology (including immature sacrococcygeal teratoma)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Tumors can occur in testicular, ovarian or extragonadal primary locations
- Sex cord stromal tumors (granulosa cell, theca, sertoli, and leydig tumors) are rare in pediatrics and should be imaged according to general guidelines in: **Testicular, Ovarian and Extragonadal Germ Cell Tumors (ONC-20)** in the Oncology Imaging Guidelines
- This section applies to primary germ cell tumors occurring outside the central nervous system in children who are ≤15 years old at the time of initial diagnosis.
  - For individuals who are >15 years old at diagnosis, the overall prognosis is inferior and these individuals should be imaged according to general guidelines in: **Testicular, Ovarian and Extragonadal Germ Cell Tumors (ONC-20)** in the Oncology Imaging Guidelines.
- For CNS germ cell tumors, use the imaging guidelines in: **CNS Germinomas and Non-Germinomatous Germ Cell Tumors (NGGCT) (PEDONC-4.7)**.

Treatment Considerations:

- Overall treatment strategies are similar for all malignant germ cell tumors.
- Individuals with localized GCT are often cured with surgery alone and do not receive adjuvant therapy.
  - These individuals should be imaged using surveillance guidelines after surgery is completed.
- Individuals receiving adjuvant chemotherapy are usually treated with 4 to 6 cycles of combination chemotherapy.

Imaging Modality Considerations:

- Initial evaluation of: Ovarian, testicular, and abdominal extragonadal suspected GCT should be completed by ultrasound and tumor markers (AFP, β-hCG)
  - Once a primary mass suspected to be GCT is discovered, initial staging is indicated prior to histologic confirmation
  - The degree of abdominal exploration and node sampling necessary for adequate staging is determined in part by imaging findings and is required for preoperative planning
- The primary method of response assessment is by tumor marker decrease
- The primary method of surveillance in pediatric GCT is frequent assessment of serum tumor markers, unless tumor markers were not elevated at diagnosis
- Surveillance imaging of the chest in disease stages I-IV should generally be performed using chest x-ray
  - See surveillance indications for specific imaging recommendations
- There has been no published evidence to date supporting the routine use of PET/CT in the evaluation of pediatric GCT

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Additionally, PET has been found to have similar efficacy to CT imaging in initial staging of adults with non-seminomatous GCT (the majority of pediatric GCT are non-seminomatous)
- PET as a marker of treatment response has been shown not to be predictive of individual outcomes in GCT and should not be approved
  - Suspicious lesions seen on conventional imaging should be biopsied to confirm active disease

Pediatric Liver and Pancreatic Tumors – General Considerations (PEDONC-11.1)

ONCP.LT.0011.1.A

v2.0.2026

- Primary hepatic germ cell tumors should follow imaging guidelines in: **Pediatric Germ Cell Tumors (PEDONC-10)**.
- Primary hepatic sarcomas should follow imaging guidelines in: **Non-Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS) (PEDONC-8.3)**.
- Imaging requests relating to liver transplant surgery and surveillance should follow guidelines in section **Transplant (AB-42)** in the Abdomen Imaging Guidelines.

Hepatoblastoma (PEDONC-11.2)

ONCP.LT.0011.2.A
v2.0.2026

Hepatoblastoma Initial Staging:

- Ultrasound is medically necessary even after MRI or CT imaging in order to allow evaluation for tumor thrombus
- Once a primary liver mass is discovered, definitive imaging is medically necessary prior to histologic diagnosis, and may involve ANY of the following:
  - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) for evaluating tumor margins and vascular anatomy
    - Hepatobiliary-specific contrast agents (gadoxetate, gadobenate [MultiHance]) are preferred if available and are medically necessary if requested, whether or not a prior gadolinium-enhanced MRI has been previously performed
    - CT Abdomen and Pelvis with (CPT® 74177) is inferior to MRI for pediatric liver malignancies and is only medically necessary if MRI is not available, contraindicated, or sedation is required but not available, or to clarify specific inconclusive areas on MRI.
      - Non-contrast imaging is not medically necessary due to the increased radiation exposure and limited additive benefit
  - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) to evaluate vascular invasion
- CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) is medically necessary in the initial work-up of all pediatric liver tumors and should be completed prior to anesthesia exposure if possible
- Bone scan (See: **Modality General Considerations (PEDONC-1.3)**) is medically necessary for initial evaluation of bony metastases only with systemic symptoms or bone pain.
- MRI Brain without and with contrast (CPT® 70553) is medically necessary only for symptoms suggesting CNS metastases
- PET/CT is medically necessary only in very rare circumstances for preoperative planning when MRI and CT scans are insufficient for surgical decision-making.
  - Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**

Hepatoblastoma Treatment Response:

- CT Chest with (CPT® 71260) **or** without contrast (CPT® 71250) is medically necessary every 2 cycles **and** at the end of planned therapy for individuals with incomplete resection at initial diagnosis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary every 2 cycles **and** at the end of planned therapy for individuals with incomplete resection at initial diagnosis
  - CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen and Pelvis without and with contrast (CPT® 74178) is inferior to MRI for pediatric liver malignancies and is only medically necessary if MRI is not available, contraindicated, or sedation is required but not available, or to clarify specific inconclusive areas on MRI.
    - Non-contrast imaging is not medically necessary due to the increased radiation exposure and limited additive benefit
- While the majority of individuals will require abdomen and pelvis imaging at all time points, the pelvis imaging may be omitted at the discretion of the ordering physician
- MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) is medically necessary to evaluate vascular invasion
- Imaging of any metastatic sites with the same modality used during initial staging is medically necessary every 2 cycles and at the end of planned therapy for individuals with incomplete resection at initial diagnosis
- Imaging is medically necessary more frequently to assess for surgical resectability in individuals who have received more than 4 cycles of chemotherapy.
- Abdominal ultrasound is medically necessary if tumor thrombus was detected at initial diagnosis
  - If no tumor thrombus was present, continued ultrasound evaluations are not medically necessary without a specific reason documented in the clinical records
- PET/CT is medically necessary only in very rare circumstances for preoperative planning when MRI and CT scans are insufficient for surgical decision making.

Hepatoblastoma Surveillance Imaging:

- For surveillance in individuals with an AFP of >100 ng/ml, the following imaging is medically necessary:
  - CT Chest with contrast (CPT® 71260) and MRI Abdomen without and with contrast (CPT® 74183) for any clinically significant rise in tumor markers or symptoms suggesting recurrent disease.
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is inferior to MRI for pediatric liver malignancies and is only medically necessary if MRI is not available, contraindicated, or sedation is required but not available, or to clarify specific inconclusive areas on MRI.
      - Non-contrast imaging is not medically necessary due to the increased radiation exposure and limited additive benefit
- For individuals with AFP ≤100 ng/ml at diagnosis or recurrence, the following imaging is medically necessary:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI Abdomen with and without contrast (CPT® 74183) every 3 months for 2 years, then every 4 months for 2 years after completion of all therapy
- Chest x-ray or CT Chest with contrast (CPT® 71260) every 3 months for 2 years, then every 4 months for 2 years after completion of all therapy
- Individuals with brain or bone metastases should have surveillance imaging on the same schedule as the primary site imaging with the same modality used during initial staging

Background and Supporting Information

- Pediatric liver tumors primarily include hepatoblastoma and hepatocellular carcinoma, but hepatic germ cell tumors and primary hepatic sarcomas occur with some frequency. Tumor markers are useful for initial evaluation as well as treatment response, particularly in hepatoblastoma. Early consideration of liver transplant may be undertaken in children and adolescents with unresectable localized disease, provided that the disease remains confined to the liver.
- Hepatoblastoma occurs most commonly in very young children (median diagnosis age of 19 months). Most cases of hepatoblastoma are sporadic, but some are associated with genetic abnormalities, including Beckwith-Wiedemann syndrome, familial adenomatous polyposis, and trisomy 18. Most suspected liver tumors will have ultrasound and tumor markers (AFP, β-HCG, CEA) as part of the initial evaluation.
- There has been no published evidence to date supporting the routine use of PET/CT imaging in the evaluation of pediatric Hepatoblastoma during initial imaging, treatment response, or surveillance.
- PET/CT should not be approved in lieu of biopsy of suspicious lesions
- Individuals with localized hepatoblastoma of pure fetal histology are often cured with surgery alone and do not receive adjuvant therapy. These individuals should be imaged using surveillance guidelines after surgery is completed.
- Individuals receiving adjuvant chemotherapy are usually treated with 2 to 8 cycles of combination chemotherapy. Tumor marker decrease is important in response assessment but does not eliminate the need for advanced imaging in individuals with unresected hepatoblastoma.
- The primary method of surveillance in hepatoblastoma is frequent assessment of serum tumor markers (primarily AFP).
- No specific imaging for surveillance in individuals with an AFP of >100 ng/mL at diagnosis or recurrence.

Pediatric Hepatocellular Carcinoma (HCC) (PEDONC-11.3)

ONCP.LT.0011.3.A
v2.0.2026

Pediatric HCC Initial Staging:

- Ultrasound is medically necessary even after MRI or CT imaging in order to allow evaluation for tumor thrombus
- Once a primary liver mass is discovered, definitive imaging prior to histologic diagnosis including ANY of the following medically necessary studies:
  - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
    - Hepatobiliary specific contrast agents (gadoxetate, gadobenate [MultiHance]) are preferred if available and are medically necessary if requested, whether or not a prior gadolinium-enhanced MRI has been previously performed.
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is inferior to MRI for pediatric liver malignancies and is only medically necessary if MRI is not available, contraindicated, or sedation is required but not available, or to clarify specific inconclusive areas on MRI.
      - Noncontrast imaging is not medically necessary due to the increased radiation exposure and limited additive benefit
  - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) to evaluate vascular invasion
- CT Chest with (CPT® 71260) **or** without contrast (CPT® 71250) is medically necessary in the initial work-up of all pediatric liver tumors and should be completed prior to anesthesia exposure if possible
- MRI Brain without and with contrast (CPT® 70553) is medically necessary only for symptoms suggesting CNS metastases
- Nuclear bone scan (See **Modality General Considerations (PEDONC-1.3)**) is medically necessary for initial evaluation of bony metastases only in individuals with systemic symptoms or bone pain
- PET/CT is medically necessary in very rare circumstances for preoperative planning when MRI and CT are insufficient for surgical decision-making.
  - PET/CT should not be approved in lieu of biopsy of suspicious lesions
  - Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Pediatric HCC Treatment Response:

- For individuals with disease not completely resected at initial diagnosis, the following imaging is medically necessary every 2 cycles (~6 weeks) **and** at the end of planned therapy:
  - CT Chest with (CPT® 71260) **or** CT Chest without contrast (CPT® 71250)
  - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
    - While the majority of individuals will require abdomen and pelvis imaging at all time points, the pelvis imaging may be omitted at the discretion of the ordering physician
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is inferior to MRI for pediatric liver malignancies and is only medically necessary if MRI is not available, contraindicated, or sedation is required but not available, or to clarify specific inconclusive areas on MRI.
      - Non-contrast imaging is not medically necessary due to the increased radiation exposure and limited additive benefit
      - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) to evaluate vascular invasion
- Imaging of any metastatic sites with the same modality used during initial staging is medically necessary
- Abdominal ultrasound is medically necessary if tumor thrombus was detected at initial diagnosis
  - If no tumor thrombus was present, continued ultrasound evaluations are not medically necessary without a specific reason documented in the clinical records
- PET/CT is medically necessary in very rare circumstances for preoperative planning when MRI and CT scans are insufficient for surgical decision-making.

Pediatric HCC Surveillance Imaging:

- MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary every 3 months for 1 year, then every 6 months for 1 year, then annually for 3 years after completion of all therapy
- Chest x-ray or CT Chest with contrast (CPT® 71260) is medically necessary every 3 months for 1 year, then every 6 months for 1 year, then annually for 3 years after completion of all therapy

Background and Supporting Information

- Individuals with brain or bone metastases should have surveillance imaging on the same schedule as the primary site imaging with the same modality used during initial staging.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- HCC, including its rare histologically distinct variant fibrolamellar hepatocellular carcinoma (FL-HCC), occurs mostly in older children and adolescents. Despite recent advances in treatment, overall survival of pediatric HCC diagnosed in advanced stages remains exceedingly poor, with five-year survival of only 17% to 22% for all stages of pediatric HCC (and FL-HCC). Most suspected liver tumors will have ultrasound and tumor markers (AFP, β-HCG, CEA) as initial evaluation.
- PET/CT should not be approved in lieu of biopsy of suspicious lesions
- The majority of hepatocellular carcinoma individuals are treated with surgery alone and do not receive adjuvant therapy. Individuals with successful upfront gross total resection should be imaged using surveillance guidelines after surgery is completed.
- PET/CT has no documented role in the surveillance evaluation of pediatric hepatocellular carcinoma.

Proprietary Information of UnitedHealthcare.

Pediatric Pancreatic Carcinoma (PEDONC-11.4)

ONCP.LT.0011.4.A
v2.0.2026

- This guideline applies to suspected or diagnosed pancreatic neoplasms in children.
- Beckwith-Wiedemann syndrome increases pancreatoblastoma risk. MEN1, VHL, neurofibromatosis, and tuberous sclerosis are also risk factors for pancreatic endocrine neoplasms.
  - Screening studies in these conditions are found in **Screening Imaging in Cancer Predisposition Syndromes (PEDONC-2)**.

Indication	Medically Necessary Imaging Study
Initial Staging	▪ CT Abdomen and Pelvis with or without and with contrast (CPT® 74177 or CPT® 74178) OR MRI Abdomen without and with contrast plus MRI Pelvis with and without contrast (CPT® 74183 and CPT® 72197) ▪ CT Chest with (CPT® 71260) or without (CPT® 71250) contrast ▪ ^{68}Ga-Dotatate PET/CT whole-body (CPT® 78816) - Exception: for pediatric pancreatic tumor of non neuroendocrine origin (SPN, pancreatoblastoma and other exocrine origin) with equivocal conventional imaging, FDG PET/CT whole-body or skull to thighs (CPT® 78816 or 78815)
Treatment response ~every 2 cycles during treatment and at the end of planned therapy	▪ CT or MRI as used at time of initial imaging
If conventional imaging for treatment response is equivocal	▪ Neuroendocrine tumors: ^{68}Ga Dotatate PET/CT skull to thighs or whole-body (CPT® 78815 or 78816) ▪ Non-neuroendocrine tumors: FDG PET/CT skull to thighs or whole-body (CPT® 78815 or 78816)
Assess candidacy for PRRT therapy	▪ ^{68}Ga Dotatate PET/CT whole body CPT® 78816 to assess candidacy for PRRT therapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Surveillance	▪ MRI or CT, modality and contrast as used in initial imaging, every 3 months for 2 years, then every 4 months for 1 year, then every 6 months for 1 year, then in 12 months to complete 5 years surveillance.
Suspected recurrence	▪ Repeat all imaging as noted in initial staging section

Background and Supporting Information

- Pancreatic tumors in children are exceedingly rare. The most common are solid pseudopapillary neoplasm (SPN), a low-grade epithelial malignancy. Pancreatoblastoma is the second most common.

Retinoblastoma – General Considerations (PEDONC-12.1)

ONCP.EC.0012.1.A
v2.0.2026

- Retinoblastoma (RB) is primarily a disease of the infant and young child, and presents with leukocoria (loss of red reflex).
- About 75% of individuals are diagnosed before the age of two years (bilateral RB presents at 12 months of age).
- Retinoblastoma can occur as heritable (25% of cases) or nonheritable (75%) disease.
  - Heritable RB is associated with a germline mutation in the RB1 gene often resulting typically in bilateral disease.
  - Individuals who carry the RB1 mutation also have increased risk of developing other cancers, such as osteosarcoma, soft tissue sarcomas, or melanoma. For more information on heritable retinoblastoma, see: **Familial Retinoblastoma Syndrome (PEDONC-2.12)**.
  - Whole-body MRI has shown poor sensitivity and specificity in individuals with predisposition to systemic malignancy due to germline RB1 mutations, and is not supported.
- Detailed evaluation by a physician with significant training and/or experience in retinoblastoma (most commonly a pediatric ophthalmologist or pediatric oncologist) is indicated prior to considering advanced imaging.
- Retinoblastoma can be unilateral, bilateral, or trilateral (involving the pineal gland). Extraocular spread of retinoblastoma is rare and generally confined to the brain.

Retinoblastoma – Imaging (PEDONC-12.2)

ONCP.EC.0012.2.A
v2.0.2026

Retinoblastoma Medically Necessary Initial Staging Imaging:

- Tumor biopsy is NOT required prior to imaging
- MRI Orbits (CPT® 70543) and Brain (CPT® 70553) without and with contrast in the initial work-up
  - Brain imaging may be omitted or deferred at the discretion of the treating ophthalmologist or oncologist
- MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) if there is evidence of CNS metastasis on:
  - Ophthalmologic exam
  - MRI Brain
  - Lumbar CSF cytology
- CT Chest (CPT® 71260) and MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) with clinical symptoms to suggest metastatic disease
- CT Orbital (contrast as requested) and orbital ultrasound if ordered by the treating ophthalmologist for a specified indication
- Nuclear bone scan (See: **Modality General Considerations (PEDONC-1.3)**) for individuals with systemic bone pain suggestive of bony metastases
- PET has no documented role in the evaluation of retinoblastoma

Retinoblastoma Medically Necessary Treatment Response Imaging:

- MRI Orbits (CPT® 70543) and/or Brain (CPT® 70553) every 2 cycles (~ every 6 weeks) and at the end of planned therapy
- For individuals with metastatic disease, imaging of known positive areas using the same modality at initial staging every 2 cycles (~6 to 8 weeks) and at the end of planned therapy

Retinoblastoma Medically Necessary Surveillance Imaging:

- Unilateral retinoblastoma
  - Surveillance using advanced imaging for unilateral retinoblastoma after enucleation or exenteration only for evaluation of specific clinical concerns.
- Bilateral retinoblastoma or individuals treated with ocular salvage approach

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI Orbits (CPT® 70543) and Brain (CPT® 70553) for individuals undergoing ocular salvage treatment approaches every 6 months for 2 years following completion of therapy or until the age of 5 years, whichever is later

Background and Supporting Information

- CT should generally be avoided in retinoblastoma individuals under one year of age or with family history of retinoblastoma (heritable) due to substantially increased risks for secondary malignancy
- The primary method of surveillance in retinoblastoma is examination under anesthesia (EUA), although some older children can be sufficiently evaluated by exam without anesthesia (EWA).
- Surveillance using advanced imaging is generally not indicated for unilateral retinoblastoma after enucleation or exenteration but can be approved for evaluation of specific clinical concerns.
- Individuals with bilateral retinoblastoma or germline mutation in RB1 are at increased risk for subsequent pineoblastoma
- Routine MRI follow up for pineal disease is not currently supported by evidence in unilateral retinoblastoma individuals without germline RB1 mutations

Pediatric Nasopharyngeal Carcinoma – General Considerations (PEDONC-13.1)

ONCP.NC.0013.1.A

v2.0.2026

- Pediatric nasopharyngeal carcinoma (NPC) is rare in comparison to adult NPC but is responsible for up to 50% of nasopharyngeal cancers in children and has higher rates of aggressive type III EBV-associated histology than adult NPC.
- Standard upfront treatment in pediatric NPC consists of 3 to 4 cycles of neoadjuvant chemotherapy followed by definitive chemoradiotherapy. Rare individuals with lower stage disease may be treated with radiotherapy alone.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pediatric NPC – Imaging (PEDONC-13.2)

ONCP.NC.0013.2.A
v2.0.2026

Pediatric NPC Medically Necessary Initial Staging Imaging:

- MRI Brain without and with contrast (CPT® 70553) **and** MRI Neck without and with contrast (CPT® 70543)
  - CT Head without and with contrast (CPT® 70470), CT Maxillofacial without and with contrast (CPT® 70488), **and/or** CT Neck with contrast (CPT® 70491) for individuals with documented contraindication to MRI imaging (avoidance of sedation should not be the sole reason)
- CT Chest with contrast (CPT® 71260) in initial staging
- Whole-body PET/CT (CPT® 78816) after histologic confirmation of NPC to evaluate for distant metastases
  - Bone scan when PET/CT is unavailable (See: **Modality General Considerations (PEDONC-1.3)**)
  - Indications and coding for rare circumstances where PET/MRI is medically necessary are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**
  - CT Abdomen with contrast (CPT® 74160) for ANY of the following if PET/CT unavailable:
    - Initial EBV DNA load ≥4000 copies/mL
    - Signs and symptoms of liver disease (including abdominal pain and elevated LFTs)

Pediatric NPC Medically Necessary Treatment Response Imaging:

- MRI Brain without and with contrast (CPT® 70553) **and** MRI Neck without and with contrast (CPT® 70543) for response assessment at the following time points:
  - Following completion of neoadjuvant chemotherapy
  - Following completion of chemoradiotherapy
- CT Chest with contrast (CPT® 71260) **and** Whole-Body PET/CT (CPT® 78816) **or** bone scan (See: **Modality General Considerations (PEDONC-1.3)**) at the following time points:
  - Following completion of neoadjuvant chemotherapy only if positive at initial diagnosis
  - Following completion of chemoradiotherapy
- PET during active treatment for recurrent pediatric cancer in rare circumstances when results are likely to result in a treatment change, including a change from active treatment to surveillance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pediatric NPC Medically Necessary Surveillance Imaging:

- MRI Brain without and with contrast (CPT® 70553) **and** MRI Neck without and with contrast (CPT® 70543) every 3 months for 1 year, then every 6 months for 2 years after completion of all planned therapy
- CT Chest with contrast (CPT® 71260) every 3 months for 1 year, then every 6 months for 2 years after completion of all planned therapy

Pediatric NPC Medically Necessary Suspected Recurrence Imaging:

- MRI Brain without and with contrast (CPT® 70553) and MRI Neck without and with contrast (CPT® 70543)
  - CT Head without and with contrast (CPT® 70470), CT Maxillofacial without and with contrast (CPT® 70488), and/or CT Neck with contrast (CPT® 70491) for individuals with documented contraindication to MRI imaging
- CT Chest with contrast (CPT® 71260)
- Whole-body PET/CT (CPT® 78816) or bone scan (See: **Modality General Considerations (PEDONC-1.3)**) for histologically confirmed recurrence of NPC. These studies are also medically necessary for:
  - Clarification of specified inconclusive findings seen on conventional imaging
  - Restaging to identify sites of disease when EBV PCR levels are abnormally high and conventional imaging is negative

Background and Supporting Information

- Metastasis frequently occurs in cervical lymph nodes and retropharyngeal space. Distal metastasis usually appears in bones, lungs, mediastinum, and rarely, in the liver. In many individuals, the initial presentation is a cervical adenopathy, and diagnosis is made with a lymph node biopsy.
- Quantitative EBV DNA PCR measured at initial diagnosis, as it can serve as an effective tumor marker if elevated at initial diagnosis.
- Skull base invasion is common in pediatric NPC and has a dramatic impact on prognosis, and is more easily recognized on MRI imaging
- PET is generally not indicated during active treatment for recurrent pediatric cancer
  - Whole-body PET/CT (CPT® 78816) or bone scan (See: **Modality General Considerations (PEDONC-1.3)**) are not indicated for routine surveillance in asymptomatic individuals

Pediatric Adrenocortical Carcinoma – General Considerations (PEDONC-14.1)

ONCP.AC.0014.1.A

v2.0.2026

- Pediatric Adrenocortical Carcinoma (ACC) is a rare but aggressive tumor, with fewer than 25 cases diagnosed each year.
- Most individuals are diagnosed because of virilizing symptoms, Cushing syndrome, and rarely with feminization and hyperaldosteronism or detection on screening imaging recommended for specified cancer predisposition syndromes.
- See: **Li-Fraumeni Syndrome (LFS) (PEDONC-2.2)** and **Beckwith-Wiedemann Syndrome (BWS) (PEDONC-2.4)** for screening recommendations for individuals known to have these syndromes.

Proprietary Information of UnitedHealthcare.

Pediatric ACC – Imaging (PEDONC-14.2)

ONCP.AC.0014.2.A
v2.0.2026

- CT Abdomen without and with contrast increases radiation exposure and should not be routinely performed in a child with an adrenal lesion as washout criteria have not been validated in children

Indication	Medically Necessary Imaging Study
Initial staging	• CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast • CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183) • Nuclear bone scan (see: **(PEDONC-1.3)** for coding)
• Solitary adrenal mass >4 cm on conventional imaging and plans for aggressive surgical resection • Inconclusive findings on conventional imaging	• FDG PET/CT scan (CPT® 78815)
After complete resection, with no plans for chemotherapy or radiotherapy	• See surveillance below
Restaging, for all unresected primary or metastatic disease on chemotherapy	• Every 2 cycles (~6 weeks) during chemotherapy, and following completion of all planned chemotherapy: ◦ CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast ◦ CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183) • If positive for distant metastases at initial diagnosis: ◦ Nuclear bone scan (see: **(PEDONC-1.3)** for coding) every 2 cycles (~6 weeks) during chemotherapy and following completion of all planned chemotherapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Response assessment at the completion of radiotherapy	• CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)
Surveillance, individuals with only localized disease at diagnosis	• Every 3 months for 2 years, then every 6 months for 3 years: ◦ CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)
Surveillance, individuals with metastatic ACC	• Every 3 months for 2 years, then every 6 months for 3 years: ◦ CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast ◦ CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)
Recurrence	• CT Chest without contrast (CPT® 71250) or with (CPT® 71260) contrast • CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)
Suspected bone recurrence	• Nuclear bone scan (see: **(PEDONC-1.3)** for coding)

Background and Supporting Information

- The mainstay of treatment is surgery.
  - Chemotherapy, adrenal suppression, and radiotherapy typically follow resection.
  - Many ACC individuals are treated with surgery alone and do not receive adjuvant therapy. These individuals should be imaged using surveillance guidelines after surgery is completed.

Pediatric Melanoma and Other Skin Cancers (PEDONC-15)

ONCP.SK.0015.A

v2.0.2026

- Pediatric melanoma is historically rare but has a steadily rising incidence, especially in adolescents and young adults (AYAs). Staging is assigned using the American Joint Committee on Cancer (AJCC) staging for adult melanoma. Most cases of melanoma arising in children and AYAs (~75%) are localized at diagnosis, and approximately 90% of individuals with pediatric melanoma are amenable to radical excision. The clinical management of adolescents and young adults with melanoma is still challenging and evolving because it is difficult to diagnose, and there is no standard treatment.
- Non-melanoma skin cancers (mostly basal cell carcinoma and squamous cell carcinoma) are extremely rare in pediatric individuals. In many cases, predisposing factors such as prolonged immunosuppression, radiation therapy, chemotherapy, voriconazole use, or a combination of the factors are present, and established age-specific guidelines for management of these skin tumors do not exist.
- Imaging guidelines and treatment approaches are consistent with those used for adults with melanoma and other skin cancers, and these individuals should follow the imaging guidelines in section **Melanomas and Other Skin Cancers (ONC-5)** in the Oncology Imaging Guidelines.

Pediatric Salivary Gland Tumors and Thyroid Tumors (PEDONC-16)

ONCO.ST.0016.A
v2.0.2026

Pediatric Salivary Gland Tumors

- The majority of pediatric salivary gland tumors arise in the parotid gland. Approximately 10% to 15% of tumors arise in the submandibular, sublingual, or minor salivary glands.
- Roughly 75% of pediatric salivary gland tumors are benign, most commonly pleomorphic adenoma.
- The most common malignant tumors occurring in the salivary glands are mucoepidermoid carcinoma, adenoid cystic carcinoma, acinic cell carcinoma, undifferentiated carcinoma, and rarely adenocarcinoma.
- American Joint Committee on Cancer (AJCC) staging is used for pediatric as well as adult salivary gland tumors.
- Imaging and treatment guidelines for malignant pediatric salivary gland tumors are consistent with those used for adults with salivary gland tumors, and these individuals should follow the imaging guidelines in section **Salivary Gland Cancers (ONC-4)** in the Oncology Imaging Guidelines.

Pediatric Thyroid Tumors

- Differentiated thyroid cancers (DTC): Papillary, Follicular and Hürthle Cell are the most common childhood thyroid malignancy. Standard treatment is thyroidectomy and radioactive iodine (RAI).
- Imaging and treatment guidelines for malignant pediatric thyroid tumors are consistent with those used for adults with thyroid tumors, and these individuals should follow the imaging guidelines in section **Thyroid Cancers (ONC-6)** in the Oncology Imaging Guidelines.

Pediatric Breast Masses (PEDONC-17)

ONCP.BC.0017.A

v2.0.2026

- Ultrasound (CPT® 76641 and CPT® 76642) is the primary and medically necessary modality used for evaluation of pediatric breast masses.
- MRI has very limited utility in evaluation of pediatric breast masses prior to biopsy but may be indicated in rare cases for surgical planning when ultrasound is non-diagnostic.
- Pediatric individuals with confirmed breast cancer should be imaged according to section **Breast Cancer (ONC-11)** in the Oncology Imaging Guidelines.

Background and Supporting Information

- Less than 1% of pediatric breast lesions are malignant, and advanced imaging is generally not recommended without histological confirmation of malignancy.
- Mammography has limited utility in pediatric breast mass evaluation due to the high mammographic breast density in this age group, and the risk of the radiation exposure outweighs the benefit of this modality. As a result, mammography is NOT recommended for evaluation of pediatric or adolescent breast masses.
  - BI-RADS classification may overstate the risk of malignancy or need for biopsy in pediatric individuals.

Histiocytic Disorders – General Considerations (PEDONC-18.1)

ONCP.HC.0018.1.A

v2.0.2026

- The majority of histiocytic disorders occurring in the pediatric population are either Langerhans Cell Histiocytosis (LCH) or Hemophagocytic Lymphohistiocytosis (HLH).
- The Non-Langerhans cell histiocytoses encompass a variety of diseases and have limited imaging considerations except as specified later in this section.
- Where there are indications for PET/CT in these guidelines, please note that indications and coding for rare circumstances where PET/MRI may be approved are found in **PET Imaging in Pediatric Oncology (PEDONC-1.4)**
- PEDONC-18 applies to individuals of all ages.
- The use of PET in this guideline refers to Fluorodeoxyglucose (fluorine-18-2-fluoro-2-deoxy-D-glucose [FDG]) radiotracer only.

Langerhans Cell Histiocytosis (LCH) (PEDONC-18.2)

ONCP.HC.0018.2.A
v2.0.2026

LCH Medically Necessary Initial Imaging:

- Whole-body PET/CT (CPT® 78816)
  - Whole-body Tc-99m bone scan (CPT® 78306) if PET is unavailable
- CT Chest with contrast (CPT® 71260) **or** high-resolution CT Chest without contrast (CPT® 71250) in addition to PET/CT for suspected pulmonary LCH based on ANY of the following:
  - Abnormal CXR
  - Symptoms of pulmonary involvement and normal CXR
  - Clarification of pulmonary findings on PET/CT
- MRI Brain without and with contrast (CPT® 70553) for ANY of the following:
  - Headaches or visual or neurologic disturbances
  - Polyuria/polydipsia or other endocrine abnormalities
  - Skull or craniofacial (including jaw) bone involvement
  - Otorrhea or hearing loss (CT Temporal Bone may be substituted if requested)
  - Other signs or symptoms suggesting intracranial involvement, including neurodegeneration syndrome
- CTA/MRA Head (CPT® 70496/70544) for operative planning or image guidance
- CT Abdomen and/or Pelvis with contrast (CPT® 74177, 74160, or 72193) for ANY of the following:
  - Abdominal and/or pelvic signs and symptoms **if PET/CT has not been performed** or to clarify abnormal abdominal/pelvic findings on PET/CT
  - Abdominal and/or pelvic findings on ultrasound if PET/CT has not been performed
- MRI Abdomen without and with contrast (CPT® 74183) for any of the following:
  - Elevated liver function tests (usually >5X upper limit of normal)
  - Abnormalities seen on abdominal ultrasound or CT
- MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) for ANY of the following **if PET/CT has not been performed**:
  - Vertebral lesions seen on skeletal survey
  - Clinical symptoms (including back pain) suggesting spinal involvement and negative skeletal survey

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

LCH Medically Necessary Treatment Response Imaging:

- Both PET/CT and CT with contrast or MRI without and with contrast **only** for simultaneous treatment response evaluation with specific documentation showing that both are necessary (i.e., not for purpose of acquiring a PET/MRI)
- CT and/or MRI and/or PET/CT (if modality showed disease at initial diagnosis):
  - After 2-3 cycles of treatment
  - At completion of therapy (approximately 12 weeks) for individuals with persistent disease on cycle 2-3 imaging
  - After surgical curettage (CT or MRI of involved area, not repeat PET)
  - After radiation therapy
- Following the initial phase, treatment response evaluation of **involved sites** with CT with contrast or MRI with and without contrast, every ~3 months while receiving active treatment and at completion of therapy.
  - PET/CT for inconclusive conventional imaging, if disease was previously only measured/measurable on PET/CT, or for change from active treatment to surveillance
  - Shorter interval imaging for documented signs or symptoms concerning for disease progression

LCH Medically Necessary Surveillance Imaging:

- Surveillance imaging is determined by areas of disease involvement.
  - Bone involvement
    - Single site bone disease
      - Every 3 months for 1 year after completion of therapy:
        - PET/CT (CPT® 78815 or CPT® 78816)

          OR
        - CT or MRI contrast as requested of involved bony areas
    - Multifocal bone disease
      - Every 3 months for 2 years, then no more than annually:
        - PET/CT (CPT® 78815 or CPT® 78816)

          OR
        - CT or MRI contrast as requested of involved bony areas
    - Skull or craniofacial (including jaw) bone involvement should be imaged according to CNS involvement section below.

  Individuals with lung, CNS, and/or liver involvement are considered to have high-risk disease and warrant site-specific diagnostic imaging in addition to PET/CT as outlined below:
- Pulmonary involvement

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- CT Chest with (CPT® 71260) **or** without contrast (CPT® 71250) every 6 months for the first 2 years post completion of therapy for any of the following:
  - Individuals with a history of pulmonary involvement
  - Individuals with new respiratory or chest symptoms
  - New findings on CXR

  AND
- PET/CT (CPT® 78815 or CPT® 78816) every 6 months for 2 years, then no more than annually

- CNS involvement
  - PET/CT (CPT® 78815 or CPT® 78816) every 6 months for 2 years, then no more than annually

    AND
  - MRI Brain without and with contrast (CPT® 70553) at 6 weeks, and then every 6 months for 2 years after completion of all therapy for previously documented measurable intracranial lesions
    - If negative after two years, MRI Brain without and with contrast (CPT® 70553) at 4, 7, and 10 years after completion of all planned therapy
    - If residual measurable intracranial lesions are present at 6 months, imaging repeated every 3 months until negative or unchanged on two consecutive studies, at which time the schedule in the previous bullet should begin
  - MRI Brain without and with contrast (CPT® 70553) for documented hypothalamic-pituitary dysfunction every 6 months for 2 years and at 4, 7, and 10 years after completion of all planned therapy
    - MRI at any time for worsening neurologic symptoms
  - Intraspinal lesions imaged according to the same timeframes as brain imaging using MRI without and with contrast of all involved spine levels
- Liver involvement
  - For individuals with a history of liver involvement, ONE of the following every 6 months for 2 years after completion of all therapy:
    - Ultrasound Abdomen (CPT® 76700)
    - CT Abdomen with contrast (CPT® 74160)
    - MRI Abdomen without and with contrast (CPT® 74183)

    AND
  - PET/CT (CPT® 78815 or CPT® 78816) every 6 months for 2 years, then no more than annually
- Suspected recurrence or inconclusive findings on any surveillance imaging:
  - All imaging studies supported for initial workup including whole-body PET/CT (CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- This guideline may be used for all ages of individuals.
- LCH includes a heterogeneous group of disorders formerly known by other names, including histiocytosis X, eosinophilic granuloma, Letterer-Siwe Disease, Hand-Schuller-Christian Disease, and diffuse reticuloendotheliosis. LCH has a widely variable clinical presentation, ranging from single indolent lesions to disseminated multisystem disease.
- Most common sites of involvement are skin, bones, liver, lung, and pituitary, though other sites are possible.
- Individuals with localized or single site disease are often treated only with local therapies or observed, and should be imaged according to surveillance guidelines
- Individuals receiving systemic therapy will usually undergo treatment for ~12 months. Treatment response is assessed using any modalities showing disease at initial diagnosis after ~6 weeks of treatment.
- Skull or craniofacial (including jaw) bone involvement at diagnosis are at higher risk for CNS recurrence
- CNS LCH has a particularly high rate of refractory and recurrent disease, and requires longer imaging surveillance
- Liver involvement
  - Persistent liver involvement is rare, and imaging after completion of LCH therapy will be highly individualized depending on degree of liver dysfunction and plans for supportive therapy or liver transplant

Hemophagocytic Lymphohistiocytosis (HLH) (PEDONC-18.3)

ONCP.HC.0018.3.A

v2.0.2026

- As imaging for this condition is usually done on an urgent basis, ANY or ALL of the following are medically necessary for the initial evaluation of HLH include:
  - Ultrasound Abdomen (CPT® 76700)
  - CT Abdomen and/or Pelvis (contrast as requested)
  - MRI Abdomen (CPT® 74183) and/or Pelvis (CPT® 72197) without and with contrast
  - Chest x-ray
  - CT Chest with contrast (CPT® 71260)
  - MRI Brain without and with contrast (CPT® 70553)
  - CTA/MRA Head (CPT® 70496/CPT® 70544) for operative planning or image guidance
  - CT Sinus without or with contrast (CPT® 70486 or CPT® 70487) if clinical suspicion for sinus disease
- Whole-body PET/CT (CPT® 78816) for the purpose of identifying a site for tissue diagnosis of a primary source of infection or malignancy if conventional imaging has been completed and is unrevealing
  - If a malignancy is identified as the inciting factor for HLH, additional imaging decisions for that malignancy should be based on the appropriate diagnosis-specific guidelines

Background and Supporting Information

- There are no standard imaging studies required for the diagnosis and initial evaluation of HLH. Most cases are diagnosed with a combination of physical findings, laboratory testing, and bone marrow evaluation. Advanced imaging studies may be necessary to assess organ dysfunction as HLH commonly affects the liver, spleen, and bone marrow, and less commonly the kidneys, lungs, and brain
- It is NOT required to perform ultrasound or plain film in a stepwise fashion if CT or MRI is planned as individuals with HLH can deteriorate rapidly
- There is no established standard role for PET in the diagnosis or treatment response evaluation of HLH
  - Secondary HLH is very difficult to treat if the primary cause is not concurrently treated

Non-Langerhans Cell Histiocytoses (PEDONC-18.4)

ONCP.HC.0018.4.A
v2.0.2026

Juvenile Xanthogranuloma (JXG) medically necessary imaging:

- Skin and/or cervical nodes:
  - CT with contrast of appropriate area
- Systemic JXG with multi-organ involvement:
  - MRI Brain (CPT® 70553) **and/or** Orbits (CPT® 70543) without and with contrast
  - CT Neck (CPT® 70491), Chest (CPT® 71260), **and/or** Abdomen (CPT® 74160) with contrast
  - CTA/MRA Head (CPT® 70496/CPT® 70544) may be approved as part of operative planning or image guidance
- There is no established role for PET in the diagnosis or treatment of JXG

Rosai-Dorfman Disease (RDD) medically necessary imaging:

- RDD Initial Imaging Studies:
  - MRI Brain (CPT® 70553) and/or Orbits (CPT® 70543) without and with contrast
  - CTA/MRA Head (CPT® 70496/CPT® 70544) for operative planning or image guidance
  - CT Neck (CPT® 70491), Chest (CPT® 71260) and/or Abdomen/Pelvis (CPT® 74177) with contrast **if PET/CT not performed** or to follow up unclear findings in said body areas on PET/CT
  - CT Sinus without or with contrast (CPT® 70486 or CPT® 70487) if clinical suspicion for sinus disease and **PET/CT not performed** or to follow up unclear sinus findings on PET/CT
  - Whole-body PET/CT (CPT® 78816) after histologic confirmation of diagnosis
- RDD Treatment Response:
  - Treatment response imaging after 2-3 cycles of systemic therapy during active treatment using any modalities showing disease at diagnosis, including PET/CT.
    - Once PET/CT is negative, conventional imaging with other modalities that revealed disease at presentation for subsequent restaging at completion of chemotherapy and/or radiation and/or after surgical resection.
- RDD Surveillance Imaging:
  - PET/CT (CPT® 78816) every 3 months until stabilization of disease (two PET/CT with stable disease status).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - Further surveillance imaging of single-site bone disease:
        - Every 6 months using any modalities showing disease at initial diagnosis (excluding PET/CT) for 1 year
        - PET/CT is not medically necessary for routine surveillance of RDD but is medically necessary if conventional imaging is inconclusive for suspected recurrence.
    - Further surveillance imaging of multifocal bone disease:
        - Every 6 months using any modalities showing disease at initial diagnosis (excluding PET/CT) thereafter
        - PET/CT is not medically necessary for routine surveillance of RDD but is medically necessary if conventional imaging is inconclusive for suspected recurrence.

Erdheim-Chester Disease (ECD) medically necessary imaging:

- ECD Initial Imaging Studies:
    - PET/CT Whole Body (CPT® 78816)
        - Nuclear bone scan (See: **PEDONC-1.3: Modality General Considerations)** in lieu of PET if requested
    - MRI Brain without and with contrast (CPT® 70553) **and/or** MRI Orbits (CPT® 70543) without and with contrast for CNS symptoms, including diabetes insipidus
    - CTA/MRA Head (CPT® 70496/70544) for operative planning or image guidance
    - CT Neck (CPT® 70491), Chest (CPT® 71260) **and/or** Abdomen/Pelvis (CPT® 74177) with contrast **if PET/CT not performed** or if inconclusive findings in said body area on PET/CT
    - Cardiac MRI without and with contrast (CPT® 75561) for clinically suspected cardiac involvement
    - CT Sinus without or with contrast (CPT® 70486 or CPT® 70487) if clinical suspicion for sinus disease **if PET/CT not performed** or inconclusive sinus findings on PET/CT
- ECD Treatment Response:
    - Treatment response imaging every 3 months during active treatment using any modalities showing disease at initial diagnosis, including PET/CT
    - Once PET/CT shows no remaining FDG-avid lesions, additional PET imaging is only when conventional imaging studies are inconclusive and acute treatment decisions will be made based on PET results.
- ECD Surveillance Imaging:
    - CT **and/or** MRI **and/or** Nuclear bone scan **and/or** CTA **and/or** MRA **and/or** Cardiac MRI (if modality showed disease at initial diagnosis) every 3 months until the first year after completion of treatment and then every 6 months
    - PET/CT if conventional imaging is inconclusive for suspected recurrence.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

- Non-Langerhans Cell histiocytoses includes diagnoses such as juvenile xanthogranuloma (JXG), sinus histiocytosis with lymphadenopathy (Rosai-Dorfman Disease, RDD), and Erdheim-Chester Disease (ECD)
- In general, these are localized cutaneous or nodal disease without need for regular advanced imaging, but important exceptions are listed in this section.
- Juvenile Xanthogranuloma (JXG):
  - Generally involves only skin or cervical nodes, and involutes spontaneously
- Rosai-Dorfman Disease (RDD):
  - Characterized by bulky adenopathy (usually cervical) with frequent systemic involvement
  - There is no established role for routine surveillance imaging of asymptomatic individuals after treatment for RDD
- Erdheim-Chester Disease (ECD):
  - An aggressive histiocytic disorder with overall poor prognosis that is characterized by long bone involvement with frequent spread to multiple organs
  - Most individuals will receive systemic therapy
  - Once PET/CT shows no remaining FDG-avid lesions, additional PET imaging is not indicated unless conventional imaging studies are inconclusive and acute treatment decisions will be made based on PET results.

Long Term Pediatric Cancer Survivors – General Considerations (PEDONC-19.1)

ONCP.CS.0019.1.A

v2.0.2026

- This section applies to individuals who have passed the end of the surveillance imaging period for their specific cancer, or 5 years after completion of therapy, whichever occurs first.
- As these are long-term survivors, many individuals falling under this guideline section will have reached adult age. However, these guidelines relate specifically to late effects of childhood cancer treatment and should be applied to all long-term childhood cancer survivors regardless of current age.
- The Children's Oncology Group has published comprehensive guidelines for the management of long-term childhood cancer survivors, and these are available at: http://www.survivorshipguidelines.org.
- A summary of cancer treatment should be available for all individuals in this category and should generally include, at minimum:
  - type of cancer and stage
  - dates of diagnosis, recurrence, cancer-related surgeries, beginning and end dates of chemotherapy, radiotherapy, and/or stem cell transplant
  - protocol number used for treatment and cumulative chemotherapy drug dose exposures
  - cumulative radiation dose, fraction number, modality, and field exposure
- Annual detailed history and complete physical examination is a critical component of cancer survivorship care and along with laboratory testing serves as the primary method of screening for the majority of late effects.
- Advanced imaging for asymptomatic screening is not routinely indicated except as specified in this section.
- Imaging requests related to new clinical signs or symptoms in a long term cancer survivor not explicitly covered in this section should be reviewed according to the guideline for the individual's cancer type or the relevant non-malignant clinical problem.

Cardiotoxicity and Echocardiography (PEDONC-19.2)

ONCP.CS.0019.2.A

v2.0.2026

- Screening echocardiography (CPT® 93306, CPT® 93307, or CPT® 93308) for life after exposure to anthracycline chemotherapy, cardiotoxic immunotherapy, or cardiac exposure to radiotherapy

MEDICALLY NECESSARY SCREENING ECHOCARDIOGRAM INDICATIONS			
Age at Time of Exposure	**Cumulative Doxorubicin Equivalent Dose**	**Cumulative Radiation Dose to Cardiac Muscle**	**Echocardiogram Frequency**
All ages	None	None	None
0-0.99 years	≥250 mg/m2	None	Annual
	0-249 mg/m2	Any dose	Annual
	0-249 mg/m2	None	Every 2 years
1-4.99 years	≥250 mg/m2	Any dose	Annual
	0-249 mg/m2	15+ Gy	Annual
		0-14.99 Gy	Every 2 years
	None	35+ Gy	Annual
		15-34.99 Gy	Every 2 years
		0-14.99 Gy	Every 5 years
5+ years	≥250 mg/m2	Any dose	Every 2 years
	0-249 mg/m2	15+ Gy	Every 2 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

MEDICALLY NECESSARY SCREENING ECHOCARDIOGRAM INDICATIONS			
Age at Time of Exposure	**Cumulative Doxorubicin Equivalent Dose**	**Cumulative Radiation Dose to Cardiac Muscle**	**Echocardiogram Frequency**
		0-14.99 Gy	Every 5 years
	None	35+ Gy	Every 2 years
		15-34.99 Gy	Every 5 years
		0-14.99 Gy	None
All ages with known ventricular dysfunction			Annual

- Stress echocardiography is not medically necessary as a screening study for anthracyclines cardiotoxicity in the absence of coronary artery disease symptoms. See **Stress Testing with Imaging – Indications (CD-1.4)** for imaging guidelines.
- Female cancer survivors who are pregnant or planning to become pregnant:
  - If any of the following are present, echocardiogram is medically necessary as a baseline exam and in the 3rd trimester, and as clinically indicated for symptoms (see **Pregnancy – Maternal Imaging (CD-11.4)** in the Cardiology Imaging Guidelines) if ANY of the following are present:
    - Anthracycline or cardiotoxic chemotherapy/immunotherapy exposure
    - chest radiotherapy

Background and Supporting Information

- Exposure to cardiotoxic anthracycline chemotherapy agents is common in pediatric oncology due to the high success rate of this drug class in the treatment of pediatric cancers.
- Cardiac risk is assessed based on the age of the individual at the time of treatment initiation, the cumulative drug exposure expressed as doxorubicin equivalent mg/m^2, and the presence or absence of radiotherapy exposure to cardiac muscle.

Second Malignant Neoplasms (SMN) (PEDONC-19.3)

ONCP.CS.0019.3.A
v2.0.2026

SMN—Breast Cancer

Clinical breast exam every 6 months supplemented with the following medically necessary imaging:

- MRI Breast (CPT® 77049) annually and annual mammogram beginning at age 25 or 8 years after completion of radiotherapy (whichever occurs later- screening breast MRI is not supported prior to age 25) for individuals who received therapeutic radiation exposure in the following fields while they were under 30 years of age:
  - Chest (thorax)
  - Whole lung
  - Mediastinal
  - Axilla
  - Mini-mantle, mantle, or extended mantle
  - Total (TLI) or subtotal (SLTI) lymphoid irradiation
  - Total body irradiation (TBI)

SMN – CNS Tumors

- Routine surveillance of asymptomatic individuals with normal neurologic exams is not supported by evidence and is therefore not medically necessary, with the exception of NF1 and NF2 below:
  - MRI Brain without and with contrast (CPT® 70553) is medically necessary every 2 years after completion of radiotherapy for individuals with NF1 or NF2.
- MRI Brain without and with contrast (CPT® 70553) is medically necessary for any individual with history of brain radiotherapy and new neurologic symptoms, including simple headache.
- MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar Spine (CPT® 72158) without and with contrast are medically necessary for any individual with history of spine radiotherapy and new neurologic symptoms including change in quality of pain.
  - MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) is medically necessary if being performed immediately following a contrast-enhanced MRI Brain.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- MRI Brain without and with contrast (CPT® 70553) is medically necessary annually for individuals with history of brain radiotherapy and persistent neurologic symptoms.
- MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar Spine (CPT® 72158) without and with contrast is medically necessary annually for individuals with history of spine radiotherapy and persistent neurologic symptoms.
  - MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) is medically necessary if being performed immediately following a contrast-enhanced MRI Brain.

SMN—Colorectal Cancer

- Advanced imaging is not medically necessary. See: *Background and Supporting Information* section for recommended surveillance.

Background and Supporting Information

- SMN—Breast Cancer:
  - Clinical breast exam every 6 months supplemented with advanced imaging
- SMN-CNS Tumors:
  - These are associated with radiation exposure to the brain and with neurofibromatosis
  - Routine surveillance of asymptomatic individuals with normal neurologic exams is not supported by evidence, with the exception of NF1 and NF2 listed above
- SMN—Colorectal Cancer:
  - Colonoscopy is recommended every 5 years beginning at age 30 or 5 years after radiation exposure (whichever is later) for individuals with ≥30 Gy radiation exposure to the following fields:
    - Thoracic, Lumbar, Sacral, or Whole Spine
    - Abdomen
    - Pelvis
    - Total body irradiation (TBI)
- Colonoscopy is also recommended every 5 years beginning at age 30 or 5 years after radiation exposure (whichever is later) for individuals with:
  - Personal history of ulcerative colitis, GI malignancy, adenomatous polyps, or hepatoblastoma
  - Familial polyposis
    - Family history of colorectal cancer or polyps in a first degree (parent or sibling) relative
- While the American Cancer Society recently added computed tomographic colonography (CTC) (AKA “Virtual Colonoscopy”) as an acceptable option for colorectal cancer screening of average-risk adults, the National Comprehensive Cancer Network and United States Preventive Services Task Force concluded that

data was too premature to warrant its use in screening. Colonoscopy remains the preferred screening modality for survivors at highest risk of colorectal cancer

Osteonecrosis in Long Term Cancer Survivors (PEDONC-19.4)

ONCP.CS.0019.4.A
v2.0.2026

Osteonecrosis is associated with corticosteroid, chemotherapy, and radiation exposure during treatment for ALL, NHL, and allogeneic HSCT in pediatrics. Osteonecrosis occurs primarily in hips, knees, and ankles and is frequently multifocal.

Osteoradionecrosis of the jaw can occur in individuals receiving radiotherapy to the mandible or maxilla; those receiving ≥40 Gy are at highest risk. Although unusual, it can also occur in any bone without symptoms. It is rare in other disease types.

- Plain films of symptomatic areas are indicated prior to advanced imaging.
- Routine bone density screening using DEXA or Quantitative CT screening has not been well normalized in the pediatric population, but imaging is medically necessary for those with symptoms to suggest bone density issues
  - DEXA or Quantitative CT screening is not medically necessary until age 18 unless a surgery, core decompression, or initiation of osteoporosis drugs will be planned based on the imaging results.
- Serial advanced imaging is not medically necessary in osteonecrosis without specific documentation regarding how the advanced imaging will change current individual management.
  - When advanced imaging is necessary for acute management decisions, MRI without contrast of the affected area(s) is medically necessary.
  - Surveillance imaging of asymptomatic individuals to detect osteonecrosis is not medically necessary as it has not been shown to impact individual outcomes, and it is not standard to alter treatment based on imaging findings alone without symptoms.
    - Follow-up MRI of incidentally discovered osteonecrosis findings in asymptomatic individuals has not been shown to impact individual outcomes and is not medically necessary.
    - For known osteonecrosis with articular collapse on other imaging, CT without contrast of area of interest is medically necessary for surgical planning.
- See: **Acute Lymphoblastic Leukemia (ALL) (PEDONC-3.2)** for information on imaging osteonecrosis in ALL during active treatment.

CNS vascular changes in pediatric cancer survivors following CNS radiation (PEDONC-19.5)

ONCP.CS.0019.5.A
v2.0.2026

Children receiving cranial radiation are at increased risk of cerebrovascular complications, including: hemorrhagic and ischemic stroke, moyamoya, occlusive vasculopathy, and cavernomas. These complications may occur months to years after radiation exposure.

- MRI Brain without and with contrast (CPT® 70553) and MRA Head (CPT® 70544, 70545, or 70546) are medically necessary for all individuals of any age with new neurologic symptoms or headache and a history of cranial irradiation.
- MRI Brain without and with contrast (CPT® 70553) and MRA Head (CPT® 70544, 70545, or 70546) are medically necessary annually for 10 years post treatment in individuals with a history of cranial irradiation and any of the following additional risk factors:
  - Down syndrome, sickle cell disease, or neurofibromatosis 1 or 2
  - Parasellar or suprasellar tumors (i.e., craniopharyngioma)
  - Radiation dose >50 Gy
  - Radiation field involving Circle of Willis

General Considerations (PEDONC-20.0)

ONCP.HT.0020.0.A
v2.0.2026

Transplant Types:

- Allogeneic (“allo”): The donor and recipient are different people, and there are multiple types depending on the source of the stem cells and degree of match between donor and recipient. This is most commonly used in diseases originating in the hematopoietic system, such as leukemias and lymphomas, and bone marrow failure syndromes or metabolic disorders. **The goal is to replace the hematopoietic and immune system with healthy donor cells to treat the disease.** Common types are:
  - Matched sibling donor (MSD or MRD): Donor and recipient are full siblings and HLA-matched
  - Matched unrelated donor (MUD): Donor and recipient are HLA matched but not related to each other
  - Cord blood: Donor stem cells come from frozen umbilical cord blood not related to the recipient, sometimes from multiple different donors at once
  - Haploidentical transplant (haplo): Donor is a half-HLA match to the recipient, usually a parent
- Autologous (“auto”): The donor and recipient are the same person. The process involves delivery of high dose chemotherapy that is ablative to the bone marrow, followed by an infusion of one’s own harvested stem cells. This is primarily done in the context of solid tumors and the stem cells mainly rescue hematopoiesis to facilitate high-dose chemotherapy.
- Allogeneic HSCT results in a much greater degree of immunosuppression than autologous HSCT because of the need to allow the new immune system to chimerize with the recipient’s body. Immune reconstitution commonly takes more than a year for individuals who receive allogeneic HSCT, and individuals remain at high risk for invasive infections until that has occurred. In addition, patients may require prolonged immunosuppression for prevention and management of graft-vs-host disease.
- Recipients of autologous transplant are deeply immunosuppressed until complete count recovery, which may take several months. Graft-vs-host disease is not a consideration in auto transplants because the host is also the donor.

Pre-Transplant Imaging (PEDONC-20.1)

ONCP.HT.0020.1.A
v2.0.2026

- Disease status assessment may be approved per individual disease guidelines if it has been 6 weeks or more between end of treatment imaging and HSCT or if there are signs and symptoms of disease progression.

Indication	Medically Necessary Imaging
Immediate pre-transplant period - screening for active or occult infection	• CT Chest with contrast or CT Chest without contrast (CPT® 71250 or CPT® 71260) ◦ CT Abdomen with contrast (CPT® 74160)for asymptomatic individuals if chest infection or disease is identified on CT Chest or for signs and symptoms of active abdominal infection including fever. ◦ CT Pelvis for pelvic signs and symptoms with CPT® 74177 or CPT® 72193 if abdominal imaging has already been performed. • CT Sinus (CPT® 70486) is not medically necessary for screening prior to HSCT, but is medically necessary for signs or symptoms of infectious or disease involvement of the sinuses
Individuals at risk of developing VOD, for pre-transplant baseline	• Abdominal ultrasound +/- Doppler (CPT® 76700 or 76705 +/- 93975)
Individuals with history of multiple blood transfusions at risk of iron overload, for iron quantification baseline	• CPT® codes as listed in **Transfusion-Associated (Secondary) Hemochromatosis (PEDAB-18.2)** in the immediate pre-transplant period even if done in the previous 12 months.
Suspected renal tubular dysfunction	• Nuclear renal imaging (CPT® 78700, CPT® 78701, CPT® 78707, CPT® 78708, CPT® 78709)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

- CT Sinus screening is not routinely recommended as two studies showed no utility and no effect on surgical consults.
- Changes from baseline abdominal ultrasound with regard to veno-occlusive disease (VOD) are more predictive than absolute measurements and thus baseline imaging is supported.
- Pre-transplant liver and cardiac iron levels are associated with adverse transplant outcomes and a baseline is supported for further management.

Proprietary Information of UnitedHealthcare.

Post-Transplant Imaging (PEDONC-20.2)

ONCP.HT.0020.2.A
v2.0.2026

Early post-transplant complication (<100 days post HSCT):

Indication	Medically Necessary Imaging
For signs and symptoms of pulmonary infection or pulmonary edema or new CXR abnormalities	• CT Chest without or with contrast (CPT® 71250 or CPT® 71260) ◦ For PET/CT requests to clarify infection vs malignancy, see disease-specific guidelines for equivocal conventional imaging
Suspected impending lung necrosis on other imaging	• MRI Chest without and with contrast (CPT® 71552)
• EITHER of the following: ◦ Suspected graft vs. host disease (GVHD) of chest ◦ Bronchiolitis Obliterans (BOOP/BOS)	• High-resolution CT Chest without contrast (CPT® 71250)
• ANY of the following: ◦ Suspected intra-abdominal and or pelvic infection (including cystitis or typhlitis) ◦ Suspected small bowel GVHD	• Abdominal Ultrasound (CPT® 76700 or CPT® 76705) +/- Pelvic Ultrasound (CPT® 76856 or CPT® 76857) ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) for unclear findings on ultrasound
High clinical suspicion for intra-abdominal fungal infection	• CT Abdomen and Pelvis with contrast (CPT® 74177)
Suspected hepatic veno-occlusive disease (VOD)	• Ultrasound elastography (CPT® 91200) or Abdominal Ultrasound with Doppler (CPT® 76700 or CPT® 76705)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
Suspected CNS complication including infection, hemorrhage, thrombosis, or encephalopathy	• MRI Brain without contrast or MRI Brain without and with contrast (CPT® 70551 or CPT® 70553) ◦ CT Head without contrast (CPT® 70450) in the emergent setting or for suspected acute hemorrhage ▪ Acute CT should not preclude subsequent MRI imaging ◦ For additional imaging for suspected stroke, see: **Pediatric Stroke Initial Imaging (PEDHD-12.2)** in the Pediatric Head Imaging guidelines
Suspected musculoskeletal abscess or necrotizing fasciitis	• See: **Pediatric Infection/Osteomyelitis (PEDMS-8)** in the Pediatric Musculoskeletal Imaging guidelines
Fever of unknown origin (8 or more days of temperature 38.0 C/100.4 F or higher)	• PET/CT skull to thigh (CPT® 78815) if site-specific conventional imaging, microbiologic serologic studies, echocardiogram, urinalysis, and urine culture are all non-diagnostic

Late post-transplant complication imaging (100 or more days post HSCT):

Indication	Medically Necessary Imaging
CNS complications	Same imaging as for early post-transplant
Chest complications	Same imaging as for early post-transplant
Hepatic VOD	Same imaging as for early post-transplant
Chronic GI GVHD	• CT Abdomen and Pelvis (CPT® 74177) ◦ MR Enterography (CPT® 74183 and CPT® 72197) for suspected small bowel GVHD
Suspected renal tubular dysfunction	• Nuclear renal imaging (CPT® 78700, CPT® 78701, CPT® 78707, CPT® 78708, CPT® 78709)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging
Suspected poor bone mineral density or osteonecrosis	See: **Osteonecrosis in Long Term Cancer Survivors (PEDONC-19.4)**
Suspected PTLD	See: **Post-Transplant Lymphoproliferative Disorder (PTLD) (PEDONC 5.3)**

General Guidelines (PEDPV-1.0)

PVP.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms, including a detailed history, physical examination, appropriate laboratory studies, and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MRI, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the pelvis is not supported. Advanced imaging of the pelvis is only medically necessary in individuals who have documented active clinical signs or symptoms of disease involving the pelvis.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the pelvis are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.
- Ultrasound
  - Ultrasound should be the initial imaging in most pelvic conditions to rule out those situations that do not require additional advanced imaging.
  - For those individuals who do require advanced imaging after ultrasound, ultrasound can be very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the individual.
  - CPT® codes vary by body area and presence or absence of Doppler imaging and are included in the table at the beginning of this guideline.
  - Transabdominal ultrasound is appropriate in all pediatric individuals.
  - Transvaginal (TV) ultrasound is appropriate in pediatric individuals who are sexually active or use a tampon and consent to the study. Ultrasound (complete CPT® 76856 or, limited CPT® 76857) should substitute for TV in pediatric individuals or non-sexually active adult females

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following:

Pediatric Pelvis Imaging Age Considerations (PEDPV-1.1)

PVP.GG.0001.1.A
v1.0.2026

Many conditions affecting the pelvis in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.

- Individuals who are age 18 years or younger should be imaged according to the Pediatric Pelvis Imaging Guidelines if discussed. Any conditions not specifically discussed in the Pediatric Pelvis Imaging Guidelines should be imaged according to the General Pelvis Imaging Guidelines. Individuals who are >19 years should be imaged according to the General Pelvis Imaging Guidelines, except where directed otherwise by a specific guideline section.

Pediatric Pelvis Imaging Modality General Considerations (PEDPV-1.3)

PVP.GG.0001.3.A
v1.0.2026

- Ultrasound
  - See **General Guidelines (PEDPV-1.0)**
- MRI
  - MRI Pelvis is generally performed without and with contrast (CPT® 72197) unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years) as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If multiple body areas are supported by the guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session.
  - The presence of surgical hardware or implanted devices may preclude MRI.
  - The selection of best examination may require coordination between the provider and the imaging service.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CT
  - CT Pelvis typically extends from the iliac crest to the ischial tuberosities, and CT Abdomen and Pelvis extends from the dome of the diaphragm through the ischial tuberosities.
    - In general, CT Pelvis is appropriate when evaluating solid pelvic organs.
    - In general, CT Abdomen and Pelvis is appropriate when evaluating inflammatory or infections processes, hematuria, or conditions which appear to involve both the abdomen and the pelvis.
    - In some cases, especially in follow-up of a known finding, it may be appropriate to limit the exam to the region of concern to reduce radiation exposure.
  - The contrast level in pediatric CT imaging is specific to the clinical indication, as listed in the specific guideline sections.
  - CT Pelvis or Abdomen and Pelvis may be medically necessary for further evaluation of abnormalities suggested on prior US or MRI Procedures.
  - CT may be appropriate without prior MRI or US, as indicated in specific sections of these guidelines.
  - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
  - The selection of best examination may require coordination between the provider and the imaging service.
- Nuclear Medicine
  - Nuclear medicine studies are rarely used in imaging of the pediatric pelvis but are medically necessary in rare circumstances, including the following:
    - Lymph system mapping (CPT® 78195) is medically necessary for lower extremity lymphedema with recent negative Doppler ultrasound, or a history of Milroy's disease or prior pelvic lymph node dissection.
- 3D Rendering
  - 3D Rendering indications in pediatric pelvis imaging are identical to those in the general imaging guidelines. See **3D Rendering (Preface-4.1)** in the Preface Imaging Guidelines

The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Abnormal Uterine Bleeding (PEDPV-2.1)

PVP.UB.0002.1.A

v1.0.2026

- Abnormal uterine bleeding imaging indications in pediatric individuals are very similar to those for adult individuals. See **Abnormal Uterine Bleeding (AUB) (PV-2.1)** in the Pelvis Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - Transabdominal ultrasound is appropriate in all pediatric individuals.
  - Transvaginal (TV) ultrasound is appropriate in pediatric individuals who are sexually active or use a tampon and consent to the study. Transvaginal ultrasound is generally not appropriate in pediatric individuals or in individuals who have never been sexually active.
  - MRI Pelvis without contrast or without and with contrast (CPT® 72195 or CPT® 72197) is medically necessary if ultrasound is inconclusive.

Background and Supporting Information

The causes of vaginal bleeding in children differ from those in adolescents. Vaginal bleeding after the first week or so of life but before menarche is always abnormal and warrants evaluation. Common conditions before normal menarche include vaginal foreign bodies, infections, precocious puberty, and estrogen exposure. After menarche, pregnancy and excessive menstrual bleeding (ovulatory dysfunction) must be considered.

Pelvic Inflammatory Disease (PID) (PEDPV-3.1)

PVP.ID.0003.1.A

v1.0.2026

- Pelvic inflammatory disease imaging indications in pediatric individuals are very similar to those for adult individuals. See **Pelvic Inflammatory Disease (PV-7.1)** in the Pelvis Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - Transabdominal ultrasound is appropriate in all pediatric individuals.
  - Transvaginal (TV) ultrasound is appropriate in pediatric individuals who are sexually active or use a tampon and consent to the study. Transvaginal ultrasound is generally not appropriate in individuals who are pre-pubescent or victims of abuse.
  - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) is medically necessary if ultrasound is inconclusive.
  - CT Pelvis with contrast (CPT® 72193) is medically necessary if MRI is not readily available.

Amenorrhea (PEDPV-4.1)

PVP.AA.0004.1.A

v1.0.2026

- Females with primary amenorrhea and any of the following should be evaluated initially with pelvic ultrasound (CPT® 76856 or CPT® 76857):
  - Amenorrhea is usually primary and refers to absence of menstrual periods by age 16.
    - Normal pubertal development and negative pregnancy test.
    - Transabdominal ultrasound is appropriate in all pediatric individuals.
      - Transvaginal (TV) ultrasound is appropriate in pediatric individuals who are sexually active or use a tampon and consent to the study. Transvaginal ultrasound (CPT® 76830) is medically necessary for better view of genitourinary anomalies in sexually active females.
    - Delayed puberty with follicle-stimulating hormone (FSH) or luteinizing hormone (LH) that is elevated for the individual's age and Tanner stage.
- MRI Pelvis without contrast or without and with contrast (CPT® 72195 or CPT® 72197) and/or MRI Abdomen without contrast or without and with contrast (CPT® 74181 or CPT® 74183) are medically necessary for congenital anomalies or for pre-operative planning.

Pelvic Pain/Dyspareunia, and Ovarian Torsion (PEDPV-7.1)

PVP.PP.0007.1.A

v1.0.2026

- Pelvic Pain/Dyspareunia imaging indications in pediatric individuals are identical to those for adult individuals. See **Pelvic Pain/Dyspareunia, Female (PV-11.1)** in the Pelvis Imaging Guidelines.
- Ovarian torsion in children is typically associated with a normal ovary. Spontaneous torsion of a normal ovary is more common than torsion caused by a lead mass, such as a cyst or tumor. Torsion involves both the ovary and fallopian tube and typically presents with acute of onset of lower abdominal pain, often associated with nausea or vomiting.
  - Transabdominal ultrasound (CPT® 76856) with Doppler (CPT® 93975) is appropriate in all pediatric individuals.
  - Transvaginal (TV) ultrasound (CPT® 76830) with Doppler (CPT® 93975) is appropriate in pediatric individuals who are sexually active or use a tampon and consent to the study. Transvaginal ultrasound is generally not appropriate in individuals who are pre-pubescent or have never been sexually active.

Undescended Testis (PEDPV-11.1)

PVP.UT.0011.1.A

v1.0.2026

- Males with a history of cryptorchidism (undescended testis) have a several-fold risk increase of testicular cancer. It is important to diagnose and treat this condition either by bringing the undescended testis into the scrotum, or resecting the testis.
- Pediatric-specific imaging considerations include the following:
  - Suspected undescended testis is an indication for referral to a surgical subspecialist who should make the decision or be consulted on necessary imaging studies.
- After surgical evaluation or consultation, the following imaging is medically necessary for pre-operative evaluation:
  - Scrotal ultrasound (CPT® 76870) if testis not palpable in the scrotal sac and there is concern for retractile or inguinal testis. In general CT and MRI are not medically necessary to localize non-palpable testes, as the findings would typically not alter the surgical procedure.
    - If after ultrasound there is concern for associated urogenital abnormalities, or the surgical consultant or any provider in consultation with the surgical consultant indicates that advanced imaging results would significantly alter the surgical procedure either of the studies below are medically necessary:
      - MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast
      - CT Abdomen and Pelvis with contrast (CPT® 74177)

Scrotal Pathology (PEDPV-12.1)

PVP.SP.0012.1.A

v1.0.2026

- Scrotal pathology imaging indications in pediatric individuals are very similar to those for adult individuals. See **Scrotal Pathology (PV-20.1)** in the Pelvis Imaging Guidelines.
- Pediatric-specific imaging considerations include the following:
  - Scrotal US (CPT® 76870) with Doppler (CPT® 93975 or CPT® 93976) is medically necessary for concerns of testicular torsion.
  - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) is medically necessary if torsion is unlikely on ultrasound and no surgical exploration is planned. MRI is not typically used for the acute scrotum due to the limited availability of equipment and the long examination time involved.
  - Since the acceptance of Doppler US as the primary imaging for evaluation of acute scrotum, scintigraphy is not medically necessary. The unavailability of nuclear medicine imaging in many practices and its use of ionizing radiation, its poor anatomical details, and the time required for imaging are other limiting factors.

Incontinence (PEDPV-14.1)

PVP.IN.0014.1.A

v1.0.2026

- Incontinence imaging indications in pediatric individuals are very similar to those for adult individuals. See **Urinary Incontinence/Pelvic Prolapse/Fecal Incontinence (PV-22)** in the Pelvis Imaging Guidelines.
- Most often incontinence in children is not due to a medical condition. Several uncommon disorders that can lead to urinary incontinence include a spinal cord defect such as spina bifida, ureteral duplication with ectopic insertion, and overactive bladder or dysfunctional voiding.
- No imaging is needed if primary enuresis is suspected; however, imaging evaluation may be warranted if ureteral duplication or overactive bladder or dysfunctional voiding is suspected. The physician should obtain a full medical history and urinalysis before imaging is done.
- Radiopharmaceutical urinary bladder residual study (CPT® 78730) is medically necessary for suspicion of urinary retention and a recent non-diagnostic ultrasound.
- Pediatric-specific imaging considerations include the following:
  - MRI Pelvis without and with contrast (CPT® 72197) is medically necessary if ultrasound is inconclusive or spinal abnormality is suspected.
  - CT Pelvis with contrast (CPT® 72193) is appropriate if MRI is not readily available.

Patent Urachus (PEDPV-15.1)

PVP.UR.0015.1.A

v1.0.2026

- Ultrasound pelvis (CPT® 76856) is medically necessary as the initial evaluation for patent urachus.
  - ANY of the following are medically necessary if the ultrasound is inconclusive or insufficient for preoperative planning:
    - MRI Pelvis without contrast (CPT® 72195)
    - MRI Pelvis without and with contrast (CPT® 72197)
    - CT Pelvis with contrast (CPT® 72193)
- Repeat imaging of asymptomatic individuals is not generally necessary, but is medically necessary for the following:
  - New or worsening symptoms
  - Preoperative planning

Background and Supporting Information

The urachus is a “tube” connecting the fetal bladder to the umbilical cord. It is usually obliterated during fetal growth, but if it remains patent, there can be a complete or partial connection between the bladder and the umbilicus.

Ultrasound has an accuracy greater than 90%.

General Guidelines (PEDPN-1.0)

PNP.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination since the onset or change in symptoms with a thorough neurologic examination, appropriate laboratory studies, and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MRI, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.
  - EMG may not be of clinical utility or obtainable in infants or individuals with severe developmental delay
  - EMG/NCS results may not be abnormal until 10 days after injury.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the peripheral nervous system is not supported. Advanced imaging of the peripheral nervous system is only appropriate in individuals who have documented active clinical signs or symptoms of disease involving the peripheral nervous system.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the peripheral nervous system are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Click Here to Return to the Main TOC

Age Considerations (PEDPN-1.1)

PNP.GG.0001.1.A

v1.0.2026

- Many conditions affecting the peripheral nervous system in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases that occur in both pediatric and adult populations, minor differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals who are 18 years old or younger should be imaged according to the Pediatric Peripheral Nerve and Neuromuscular Disorders Imaging Guidelines if discussed. Any conditions not specifically discussed in the Pediatric Peripheral Nerve and Neuromuscular Disorder Imaging Guidelines should be imaged according to the General Peripheral Nerve Disorder Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Peripheral Nerve and Neuromuscular Disorders Imaging Guidelines, except where directed otherwise by a specific guideline section.

Proprietary Information of UnitedHealthcare.

Modality General Considerations (PEDPN-1.3)

PNP.GG.0001.3.A
v1.0.2026

- MRI
  - MRI without and with contrast is the preferred modality for pediatric peripheral nerve imaging unless otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years) as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Recent evidence based literature demonstrates the potential for gadolinium deposition in various organs including the brain after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If multiple body areas are supported by the guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session.
- CT
  - CT is rarely used in the evaluation of pediatric peripheral nerve disorders. See specific guideline sections for indications.
- Ultrasound
  - Ultrasound is rarely used in the evaluation of pediatric peripheral nerve disorders. See specific guideline sections for indications.

Brachial Plexus (PEDPN-3)

Guideline

Brachial Plexus (PEDPN-3.1)
References (PEDPN-3)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Brachial Plexus (PEDPN-3.1)

PNP.BP.0003.1.A
v1.0.2026

Disorders of the brachial plexus can generally be identified and distinguished from lesions in other locations by clinical and electromyography/nerve conduction (EMG/NCV) examination. If the diagnosis remains unclear, advanced imaging can be helpful as a pre-operative study to evaluate the anatomy of brachial plexus lesions that should have already been defined by clinical examination. However, due to the technical challenges, EMG/NCV is not required prior to imaging in children.

- MRI is the preferred modality for imaging the brachial plexus.
  - CT is not often useful and should not be used as a substitute for MRI.
  - MRI Upper Extremity Other Than Joint without contrast (CPT® 73218) or MRI Upper Extremity Other Than Joint without and with contrast (CPT® 73220) is medically necessary for unilateral brachial plexus.
  - MRI Chest without contrast (CPT® 71550) or MRI Chest without and with contrast (CPT® 71552) is medically necessary for bilateral brachial plexus studies.
  - MRI Neck without contrast (CPT® 70540) is indicated for upper trunk lesions.
  - It is rare for more than one CPT® code to be necessary to adequately image the brachial plexus area of interest.
  - MRI Shoulder without contrast (CPT® 73221) or MRI Shoulder without and with contrast (CPT® 73223) is medically necessary in infants with brachial plexopathy due to birth trauma if requested for preoperative planning. These individuals often have glenohumeral dysplasia and require shoulder surgery.
  - MRI Cervical Spine without contrast (CPT® 72141) is medically necessary if there is clinical suspicion for cervical nerve root avulsion.
  - PET/CT skull base to mid-thigh (CPT® 78815) is appropriate if there is a contraindication to MRI in individuals with a known malignancy or post-treatment syndrome.

Background and Supporting Information

The goal of imaging is to visualize the entire course of the neural network from the preganglionic to the postganglionic segments

The MRI Chest and Neck are inherently bilateral, whereas MRI Upper Extremity is unilateral.

General Guidelines (PEDPVD-1.0)

PVDP.GG.0001.0.A
v2.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms, including a detailed history, physical examination, appropriate laboratory studies, and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) can serve as a pertinent clinical evaluation.
- The use of advanced imaging to screen asymptomatic individuals for disorders involving the peripheral vascular system is not considered medically necessary unless otherwise stated in a specific guideline section.
- Advanced imaging of the peripheral vascular system is considered medically necessary in individuals who have documented active clinical signs or symptoms of disease involving the peripheral vascular system.
- Repeat imaging studies of the peripheral vascular system are not medically necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect the individual's management or treatment decisions unless otherwise stated in a specific guideline section.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Age Considerations (PEDPVD-1.1)

PVDP.GG.0001.1.A
v2.0.2026

Many conditions affecting the peripheral vascular system in the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and general populations, differences may exist in management due to the individual's age, comorbidities, and differences in disease natural history between children and adults.

- Individuals who are 18 years old and younger should be imaged according to the Pediatric Peripheral Vascular Disease imaging guidelines if discussed. Any conditions not specifically discussed in the pediatric peripheral vascular disease imaging guidelines should be imaged according to the general peripheral vascular disease imaging guidelines. Individuals who are >18 years old should be imaged according to the general Peripheral Vascular Disease imaging guidelines, except where directed otherwise by a specific guideline section.

Modality General Considerations (PEDPVD-1.3)

PVDP.GG.0001.3.A
v2.0.2026

- MRI
  - MRI is generally performed without and with contrast unless the individual has a documented contraindication to gadolinium or otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize the individual's movement, anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years), as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this population, MRI sessions should be planned with a goal of minimizing anesthesia exposure adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition-based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast is considered medically necessary if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
      - Recent evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If multiple body areas are supported for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session.
  - The presence of surgical hardware or implanted devices may preclude MRI.
  - The selection of best examination may require coordination between the provider and the imaging service.
- CT

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - CT or CTA is considered medically necessary for further evaluation of abnormalities suggested on prior US or MRI procedures.
  - CT is considered medically necessary without prior MRI or US, especially in the following (non-exhaustive list of) settings:
    - Lymphatic malformations
    - Vascular abnormalities (including vasculitis, thrombosis, narrowing, aneurysm, dissection, and varices)
    - For pre-operative planning or assessment of post-operative complications
  - In some cases, especially in follow-up of a known finding, it may be appropriate to limit the exam to the region of concern to reduce radiation exposure.
  - CT should not be used to replace MRI in an attempt to avoid sedation unless listed as a recommended study in a specific guideline section.
  - The selection of the best examination may require coordination between the provider and the imaging service.
- Ultrasound
  - Ultrasound can be helpful in evaluating arterial, venous, and lymphatic malformations.
  - Ultrasound can be limited by the imaging window and the individual's body type.
  - CPT® codes vary by body area and presence or absence of Doppler imaging and are included in the table at the beginning of this guideline.
- 3D Rendering
  - 3D Rendering indications in pediatric imaging are identical to those in the general imaging guidelines. See **3D Rendering (Preface-4.1)** in the Preface Imaging Guidelines
- The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be indicated and warranted for specific clinical situations.

Lymphatic Malformations (PEDPVD-2.2)

PVDP.AN.0002.2.A
v2.0.2026

Initial imaging

- Ultrasound is medically necessary as an initial examination for superficial lesions.
- CT with contrast of the affected body part is medically necessary for lesions with acute enlargement and concerns for compression when MRI is contraindicated.
- MRI without contrast or without and with contrast of the affected body part is medically necessary for:
  - Lymphatic malformations involving deep tissues
  - Malformations too large to be completely imaged with ultrasound
  - Inconclusive ultrasound findings
  - Preoperative planning

Clinical changes and monitoring treatment

MRI without contrast or without and with contrast of the affected body part is medically necessary every 3 months during active treatment for individuals with aggressive lesions being treated with systemic therapy.

MRI without contrast or without and with contrast of the affected body part is medically necessary for:

- Preoperative planning
- Post-treatment evaluation

CT with contrast of the affected body part is considered medically necessary to evaluate lesions with acute enlargement and concerns for compression when MRI is contraindicated.

Surveillance

Annual surveillance imaging with MRI without contrast or without and with contrast is medically necessary when lymphatic malformations are located in body areas where growth could cause significant organ dysfunction or functional impairment (e.g. airway, intestine).

Evidence Discussion

Vascular and lymphatic malformations encompass a broad variety of conditions and have very heterogeneous natural history and treatment approaches. Lesions can be

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

divided into low flow lesions (lymphatic, capillary and venous malformations), and high-flow lesions (arteriovenous malformations and fistulas).

Lymphatic malformations are composed of dilated lymphatic channels filled with proteinaceous fluid and do not connect to normal lymphatic channels. They are typically soft, non-pulsatile masses with normal overlying skin. MRI is often used for further characterization of lymphatic malformations, especially for deep or complex lesions, providing detailed images without ionizing radiation. Large lesion characterization may be limited by ultrasound imaging window. Ultrasound is the initial imaging of choice however it is limited in evaluating malformation relationship to airway or bony structures.[1]

[1] Snyder EJ, Sarma A, Borst AJ, Tekes A. Lymphatic Anomalies in Children: Update on Imaging Diagnosis, Genetics, and Treatment. *AJR Am J Roentgenol*. 2022;218(6):1089-1101. doi:10.2214/AJR.21.27200.

Click Here to Return to the Main TOC

Venous Malformations (PEDPVD-2.3)

PVDP.AN.0002.3.A
v2.0.2026

Venous Malformation Imaging Indications

Initial imaging

- Ultrasound with Doppler is medically necessary as an initial examination for superficial lesions.
- MRI without contrast or without and with contrast of the affected body part is medically necessary for venous malformations for preoperative assessment to evaluate the extent of malformation and their relationship to normal structures.
- MRA or CTA has a limited role in evaluating most venous malformations but is considered medically necessary (contrast as requested of the affected body part) if MRI or CT is equivocal and the results will impact acute management decisions.
- CT can also be used to characterize venous malformations and their relationship to normal structures but is generally not as accurate as MRI.
  - CT with contrast of the affected body part is considered medically necessary when MRI is inconclusive or contraindicated.

Clinical changes and monitoring treatment

MRI without contrast or without and with contrast of the affected body part is medically necessary for preoperative assessment of venous malformations.

CT Chest with contrast with PE protocol (CPT® 71260) or CTA Chest (CPT® 71275) is medically necessary to evaluate for suspected pulmonary embolism in individuals with Klippel-Trenaunay syndrome and CLOVES syndrome.

Surveillance

Annual surveillance imaging is medically necessary for venous malformations located in body areas where growth could cause significant organ dysfunction or functional impairment.

Evidence Discussion

Venous malformations are slow-flow lesions characterized by dilated venous spaces and a normal arterial component. They are soft, compressible, non-pulsatile lesions that are usually blue to deep purple in color. Lesions can range from very small to large

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

infiltrating ones. Some may change size with Valsalva. These lesions can enlarge over time and become painful when associated with thrombophlebitis.[2]

Venous malformations are usually isolated, but they may be seen in multiple syndromes including Klippel-Trenaunay (KT) syndrome, Blue Rubber Bleb Nevus syndrome (BRBN), Maffucci syndrome, Proteus syndrome, Bannayan-Riley-Ruvalcaba syndrome, Parkes-Weber syndrome and congenital lipomatous overgrowth, vascular malformations, epidermal nevi and scoliosis/skeletal/spinal anomalies (CLOVES) syndrome. Both Klippel-Trenaunay syndrome and CLOVES syndrome have been found to have increased risk of venous thrombosis and pulmonary embolism, particularly after surgery or sclerotherapy.

Capillary Malformations (PEDPVD-2.4)

PVDP.AN.0002.4.A
v2.0.2026

Imaging Indications for Capillary Malformations

Initial Imaging

- MRI (without contrast or without and with contrast) is considered medically necessary to evaluate occult underlying neurologic structures associated with encephalocele, spinal dysraphism, or Sturge-Weber syndrome.

Evidence Discussion

Capillary malformations including Nevus simplex (NS) and Port wine birthmarks (PWBs) are characterized by a collection of small vascular channels in the dermis and generally do not require advanced imaging because the diagnosis is made clinically. However, MRI is considered medically necessary to evaluate underlying neurologic structures in specific cases, such as suspected Sturge-Weber syndrome.[3] Additional imaging is not considered medically necessary in the absence of other complex associated clinical findings such as Sturge-Weber syndrome (SWS) and Klippel-Trenaunay syndrome (KTS). [4]

[3] Bertino FJ, Hawkins CM. Contemporary management of extracranial vascular malformations. *Pediatr Radiol*. 2023;53:1600–1617. doi:10.1007/s00247-023-05670-1

Click Here to Return to the Main TOC

Arteriovenous Malformations (AVMs) and Fistulas (PEDPVD-2.5)

PVDP.AN.0002.5.A
v2.0.2026

Imaging Indications for AVMs and Fistulas

Initial Imaging

- Ultrasound with Doppler is medically necessary as an initial examination for superficial lesions.
- MRI without contrast or without and with contrast of the affected body part is also medically necessary to evaluate the extent of AVMs and their relationship to normal structures.
- MRA (contrast as requested) of the affected body part is medically necessary for evaluation of known AVMs.
- It is unusual for both MRI and MRA to be necessary for routine treatment response or surveillance imaging of AVMs, but both are considered medically necessary for preoperative planning.
- CT and CTA can also be used to characterize AVMs and their relationship to normal structures but is generally not better than MRI and has associated radiation risks.
  - CT with contrast and/or CTA (contrast as requested) of the affected body part is considered medically necessary when MRI and/or MRA is inconclusive or contraindicated.

Clinical changes and monitoring treatment

MRI or MRA (contrast as requested) of the affected body part is medically necessary for evaluation of treatment response.

It is unusual for both MRI and MRA to be necessary for routine treatment response or surveillance imaging of AVMs, but both may be medically necessary for preoperative planning.

CT with contrast and/or CTA (contrast as requested) of the affected body part is medically necessary when MRI and/or MRA is inconclusive or contraindicated.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Surveillance

MRI or MRA (contrast as requested) of the affected body part is medically necessary for annual surveillance of known AVMs located in body areas where growth could cause significant organ dysfunction or functional impairment.

Note:

For imaging indications specific to pulmonary AVM see **Pulmonary Arteriovenous Malformations (PEDCH-14.2)** in the Pediatric Chest Imaging guidelines, and for imaging indications specific to cerebral AVM see **Pediatric Intracranial Arteriovenous Malformations (AVM) (PEDHD-10.2)** in the Pediatric Head Imaging guidelines.

Evidence Discussion

Arteriovenous malformations are characterized by a network of multiple abnormal vascular channels interposed between enlarged feeding arteries and draining veins. The arteriovenous fistula has a single communication interposed between a feeding artery and a draining vein. The normal capillary bed is absent in both lesions. Both lesions may have an aggressive clinical course and are characterized by a reddish pulsatile mass which has a thrill or bruit. Though often recognized at birth, these lesions may grow and present near adolescence.

Vascular Tumors (PEDPVD-2.6)

PVDP.AN.0002.6.A
v2.0.2026

Imaging Vascular Tumors

Initial imaging

Any or all of the following imaging of the affected body part is considered medically necessary for the initial imaging and characterization of vascular tumors:

- Ultrasound with Doppler an initial examination
- MRI without contrast or without and with contrast to determine the extent of arteriovenous malformations and their relationship to normal structures
- MRA (contrast as requested) of the affected body part is considered medically necessary for evaluation.

CT with contrast and/or CTA (contrast as requested) of the affected body part is considered medically necessary when MRI and/or MRA is inconclusive or contraindicated.

Clinical changes and monitoring treatment

For changes in clinical status (symptoms or exam findings) related to the vascular tumor either of the following imaging is considered medically necessary:

- MRI without contrast or without and with contrast of the affected body to evaluate treatment response
- MRA (contrast as requested) of the affected body part

For preoperative planning both MRI and MRA (as requested) of the affected body part are considered medically necessary.

CT with contrast and/or CTA (contrast as requested) of the affected body part is considered medically necessary when MRI and/or MRA is inconclusive or contraindicated.

Surveillance imaging

- MRA (contrast as requested) of the affected body part is medically necessary for the surveillance of known vascular tumors.
- Imaging of vascular tumors with both MRI and MRA for routine treatment response or surveillance is not considered medically necessary.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- CT with contrast and/or CTA (contrast as requested) of the affected body part is considered medically necessary when MRI and/or MRA is inconclusive or contraindicated.

Evidence Discussion

Vascular tumors include a variety of benign, borderline, and malignant tumors, which have variable clinical courses, including but not limited to Infantile hemangiomas see **Infantile Hemangiomas (PEDPVD-5)**, Epithelioid hemangioma, Kaposiform hemangioendothelioma, Kaposi sarcoma, Epithelioid hemangioendothelioma, and Angiosarcoma of soft tissue.

Large Vessel Vasculitis (PEDPVD-3.2)

PVDP.VI.0003.2.A
v2.0.2026

Imaging Indications

Initial imaging

- ANY of the following modalities is considered medically necessary for the initial evaluation of Takayasu arteritis:
  - MRA of the affected body area(s) (contrast as requested)
  - CTA of the affected body area(s) (contrast as requested)
  - Ultrasound with Doppler of the affected body area(s)

Clinical changes and monitoring treatment

- In individuals being treated with systemic therapy, imaging (MRA or CTA or US) of the affected areas is medically necessary every 3 months to monitor active treatment for response.

Surveillance

- Imaging with MRA or CTA or US of the affected areas is medically necessary annually for surveillance of known involved body areas to detect progressive vascular damage that may require intervention.

Evidence Discussion

Takayasu arteritis is the predominant large vessel vasculitis occurring in children.

Systemic vasculitis is much less common in pediatric individuals than in adults. The diagnostic pathways and treatment options are similar for both age groups. For additional information on vasculitis see **Large Vessel Vasculitis (PVD-6.9)** in the general Peripheral Vascular Disease Imaging Guidelines.

Click Here to Return to the Main TOC

Medium Vessel Vasculitis (PEDPVD-3.3)

PVDP.VI.0003.3.A
v2.0.2026

Imaging Indications

- Some children who have had COVID 19 develop a severe inflammatory disease that can present in a similar way to Kawasaki disease or toxic shock syndrome. This syndrome has been defined by the US Centers for Disease Control and Prevention as multisystem inflammatory syndrome in children (MIS-C). See **Multisystem Inflammatory Syndrome in Children (MIS-C) (PEDCD-12)** in the Pediatric Cardiac Imaging Guideline.
- Imaging guidelines for Kawasaki Disease- see **Kawasaki Disease (PEDCD-6)** in the Pediatric Cardiac Imaging Guideline.

Initial Imaging for Polyarteritis Nodosa

- For evaluation of polyarteritis nodosa:
  - ANY of the following modalities are considered medically necessary for the initial evaluation:
    - MRA of the affected body area(s) (contrast as requested)
    - CTA of the affected body area(s) (contrast as requested)
    - Ultrasound with Doppler of the affected body area(s)

Clinical Changes and Monitoring Treatment for Polyarteritis Nodosa

- For evaluation of polyarteritis nodosa:
  - MRA or CTA or US of the affected body part is medically necessary every 3 months during active treatment with systemic therapy for treatment response.

Surveillance Imaging for Polyarteritis Nodosa

- MRA or CTA or US of the affected body part is medically necessary annually for surveillance of known involved body areas to detect progressive vascular damage that may require intervention.

Evidence Discussion

Polyarteritis nodosa and Kawasaki Disease are the primary medium vessel vasculitides occurring in children.

Small Vessel Vasculitis (PEDPVD-3.4)

PVDP.VI.0003.4.A
v2.0.2026

Imaging Indications Small Vessel Vasculitis

- Advanced imaging is not sensitive enough to detect changes in small vessels and is **not** considered medically necessary for primary assessment of any small vessel vasculitis.
- End-organ damage occurs with several of the small vessel vasculitides. Advanced imaging is considered medically necessary for the following:
  - Henoch-Schönlein Purpura (HSP) is the most common vasculitis of childhood, mainly involving small blood vessels. Ultrasound abdomen (CPT® 76700) is commonly used to evaluate possible gastrointestinal complications (including bowel wall edema and hemorrhage, and intussusception) in known or suspected HSP, and should be approved when requested for that indication.
  - Granulomatosis with polyangiitis (GPA, formerly known as Wegener's granulomatosis):
    - CT Sinuses (CPT® 70486) and/or CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is considered medically necessary in the following circumstances:
      - New or worsening clinical symptoms affecting the body area requested
      - To assess response to medical therapy when a change in treatment regimen is being considered
      - Annually to evaluate the extent of disease
  - Eosinophilic granulomatosis with polyangiitis (EGPA, formerly known as Churg-Strauss Syndrome):
    - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is considered medically necessary in the following circumstances:
      - New or worsening clinical symptoms affecting the body area requested
      - To assess response to medical therapy when a change in treatment regimen is being considered
      - Annually to evaluate the extent of disease
  - Immune complex associated small-vessel vasculitis [immunoglobulin A associated vasculitis (IgAV)]:
    - Doppler ultrasound of the affected body part (most commonly abdomen) is considered medically necessary in the following circumstances:
      - New or worsening clinical symptoms affecting the body area requested

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- To assess response to medical therapy when a change in treatment regimen is being considered
- Annually to evaluate the extent of disease

Evidence Discussion

Henoch-Schonlein Purpura (HSP) is the most common vasculitis of childhood, mainly involving small blood vessels. Imaging modalities such as ultrasound, CT, and Doppler ultrasound are used to evaluate gastrointestinal complications and monitor treatment response.

Thoracic Aortic Disease (PEDPVD-4.1)

PVDP.AD.0004.1.A
v2.0.2026

Imaging Indications for Thoracic Aortic Disease

Familial Aortopathies

- For aortopathies such as the following:
  - Marfan
  - Ehlers-Danlos (EDS)- a genetic mutation known to predispose to aortic aneurysms/ dissections (TGFBR1, TGFBR2, FBN1, ACTA2, or MYH11)
  - Loeys-Dietz
  - Familial thoracic aneurysm and dissections
- Screening: for Family history with first-degree relative of aortopathy
  - Asymptomatic individuals with no signs or symptoms of disease, whose first-degree relative has no definitive gene defect, can have screening echo (TTE) annually.
- Initial workup: Individuals with suspected aortopathies (gene positive, physical exam positive, or other findings) or definite disease associated with aortopathy
  - Echocardiogram (TTE) at the time of evaluation.
  - If the consideration is for Loeys-Dietz any of the following are considered medically necessary in addition to the TTE at the time of work up:
    - MRA or CTA Head
    - MRA or CTA Neck
    - MRA or CTA Chest
    - MRA or CTA Abdomen and Pelvis
    - MRA or CTA of area of concern when there is an incidental finding on other imaging
- Surveillance: Suspected or known disease but **normal** aortic imaging:
  - Individuals with suspected genetic aortopathies but no disease can have an echocardiogram to assess for change:
    - At 6 months
    - Then annually
  - Individuals with Loeys-Dietz can be imaged with any of the following:
    - Echocardiogram
    - MRA or CTA of (any or all):
      - Head

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

        - Neck
        - Chest
        - Abdomen
        - Pelvis
    - Individuals with Loeys-Dietz can be imaged with the above at the following intervals:
        - At 6 months
        - Then annually
- Surveillance: Suspected disease and **previous abnormal** imaging
    - Individuals with abnormal thoracic imaging can be imaged with (both):
        - Echocardiogram
        - CTA or MRA of (any):
            - Chest
            - Abdomen
            - Pelvis
            - Head (Loeys-Dietz)
            - Neck (Loeys-Dietz)
    - The above imaging is considered medically necessary as follows:
        - At the time of diagnosis
        - In 6 months after diagnosis (if older than 2 years)
        - Then as follows based on the individual's age:
            - Individual's age 0 to 2 years:
                - Every 3 months
            - Individual's age 3 to 12 years:
                - Every 6 months
            - Individual's age 13 years and older:
                - Every 12 months (if <4.5 or < 0.5 cm growth per year)
                - Every 6 months if ≥4.5 or ≥0.5 cm growth per year, or any Loeys-Dietz patient)
    - If the diameter z score is increased, then a repeat study can be done prior to the next allowed study, to assess for rate of change
- If there are symptoms of dissection, any or all of the following are considered medically necessary:
    - Echo
    - CTA or MRA of (any or all):
        - Chest
        - Abdomen
        - Pelvis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- For pediatric individual with dissection, imaging per vascular surgery and cardiology or any provider in consultation with vascular surgery at **any** interval.
- Miscellaneous syndromes with potential aortopathy as major feature of congenital heart disease
  - Individuals with Turner syndrome see section **Aortic disease in Turner Syndrome (CD-11.2.10)** in the Cardiac Imaging Guideline
  - Williams syndrome See section **LVOT lesions (PEDCD-2.4.10)** in the Pediatric Cardiology Imaging Guideline
  - Individuals with congenital heart disease would be managed based on **Imaging and Surveillance per Congenital lesion (PEDCD-2.4)** in the Pediatric Cardiology Imaging Guideline
- Miscellaneous disorders that can affect the aorta such as osteogenesis imperfecta, homocystinuria, polycystic kidney disease, pseudoxanthoma elasticum, and Hurler syndrome.
  - Screening echocardiogram yearly.
  - If positive findings, follow protocol for aortic root dilatation.
- Follow-up of thoracic aortic abnormalities related to the following conditions are addressed in other imaging guidelines:
  - Coarctation of the Aorta- See **Aortic Coarctation and IAA (interrupted aortic arch) (PEDCD-2.4.11)** in the Pediatric Cardiac Imaging Guidelines
  - Congenital rubella syndrome- See **Imaging and Surveillance per Congenital lesion (PEDCD-2.4)** in the Pediatric Cardiac Imaging Guidelines
  - Kawasaki Syndrome- See **Kawasaki Disease (PEDCD-6)**
  - Neurofibromatosis- See **General Guidelines (PEDCD-1.0)** in the Pediatric Cardiac Imaging Guidelines

Evidence Discussion

Familial aortopathies such as Marfan syndrome, Ehlers-Danlos syndrome, Loeys-Dietz syndrome, and familial thoracic aneurysm and dissections are included. Imaging modalities such as echocardiogram (TTE), magnetic resonance angiography (MRA), and computed tomography angiography (CTA) are used to evaluate the extent of aortic involvement and monitor disease progression.

Aortic Congenital Vascular Malformations (PEDPVD-4.2)

PVDP.PC.0004.2.A
v2.0.2026

Imaging Indications for Aortic Congenital Vascular Malformations

Imaging for Aortic Congenital Vascular Malformation

Description	CPT®
CT Chest with contrast	71260
CTA Chest	71275
MRA Chest	71555
Cardiac MRI without contrast	75557
Cardiac MRI without and with contrast	75561

Any of the imaging in the **above table** is medically necessary for the initial diagnosis of Congenital Aortic Vascular Malformation.

Vascular rings may impact both the esophagus and trachea. CTA or MRA of the Neck is considered medically necessary to evaluate the relationship of the aortic arch to the trachea and esophagus for surgical planning.

Evidence Discussion

Congenital Aortic Vascular Malformations can be asymptomatic or can present with impact on breathing or swallowing when there is associated compression from vascular rings. Vascular rings may impact both the esophagus and trachea. Imaging modalities such as cardiac MRI, MRA, CT, and CTA are used to evaluate these malformations and their impact on surrounding structures.[5]

Visceral Artery Aneurysms (PEDPVD-4.3)

PVDP.AD.0004.3.A
v2.0.2026

Imaging Indications for Visceral Artery Aneurysms

- Visceral artery imaging indications in pediatric individuals are identical to those for adult individuals. See **Visceral Artery Aneurysm (PVD-6.5)** in the General Peripheral Vascular Disease Imaging Guidelines.

Treatment is generally indicated for visceral aneurysms ≥2cm. Imaging of visceral artery aneurysms for initial evaluation or for treatment planning is medically necessary as follows:

- Initial imaging of calcifications seen on plain film imaging suspicious for visceral artery aneurysms (spleen, kidney, liver or intestines) with ultrasound (CPT® 76700, 76705, 93975, 93976, 93978, or 93979), **or** CTA Abdomen (CPT® 74175), **or** CT Abdomen with contrast (CPT® 74160)
- MRA Abdomen (CPT® 74185) without contrast in place of CTA or CT Abdomen in pediatric individuals or when there is a contraindication to contrast materials (i.e., renal insufficiency, contrast allergy, pregnancy)
- Ultrasound (CPT® 76700,76705, 93975, 93976, 93978, or 93979) **or** CTA Abdomen (CPT® 74175) **or** CT Abdomen with contrast (CPT® 74160) is considered medically necessary for further monitoring based on the intervals below or as determined by a vascular specialist or any provider in consultation with a vascular specialist:
  - Splenic artery aneurysms:
    - <20mm can be imaged every three years
    - 20mm to 29mm can be imaged annually
    - If ≥30mm, they should be referred for treatment, either stent, excision or splenectomy
  - For all other visceral artery aneurysms:
    - Initial evaluation with six-month follow-up for one year
    - Further follow-up annually if no significant enlargement is seen
- CTA Abdomen (CPT® 74175), MRA Abdomen (CPT® 74185), or CT Abdomen with contrast (CPT® 74160) is considered medically necessary following stent placement at:
  - 1 month
  - 6 months
  - 12 months
  - Then every year

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

Visceral artery aneurysms are rare but can be life-threatening if ruptured. Imaging indications in pediatric individuals are identical to those for adult individuals, with modalities such as MRA, CTA, and ultrasound being used for evaluation. Aneurysmal disease, besides primarily involving the large vessels, can also affect medium and smaller sized vessels. Visceral cases are uncommon and occasionally are associated with certain connective tissue and genetic disorders. They are often found incidentally on imaging. Ultrasound, CT, or CTA imaging may be indicated for surveillance in these cases. Due to the anatomic location of the visceral vessels, duplex ultrasound may have technical limitations. Consideration of best surveillance study should be decided on initial imaging and whether a certain modality is felt to provide diagnostic information. Example: some splenic arterial aneurysms may be diagnostic with US, but others may be obscured by bowel gas requiring CT/CTA.

General Considerations (PEDPVD-5.1)

PVDP.IH.0005.1.A
v2.0.2026

Most infantile hemangiomas do not require any imaging. Ultrasound with Doppler can be used when the diagnosis is uncertain, or with high-risk clinical considerations. Other general imaging considerations for other vascular neoplasms regarding MRI, MRA, CT, and CTA also apply to infantile hemangiomas. See **Imaging vascular tumors**.

- Multiple (5 or more) infantile hemangiomas can be associated with hepatic hemangiomas with risk potential for high-output cardiac failure and other risks see **Multiple Infantile Hemangiomas (PEDPVD-5.2)**.
- High-output cardiac failure can also be caused rarely by large cutaneous infantile hemangiomas. Affected infants may present with “failure-to-thrive”, a hyperdynamic precordium, tachycardia, bounding pulses with a widened pulse pressure, and a palpable thrill and/or audible bruit over the hemangioma. This is an indication for cardiac evaluation, including echocardiography (CPT® 93303 ordered with CPT® 93320 and CPT® 93325).
- Life threatening risk of airway obstruction is associated with infantile hemangiomas of the lower face (“beard distribution”), or of the anterior neck, or of the oral and/or pharyngeal mucosa.
- Location-associated functional impairment can be found with periocular infantile hemangiomas larger than 1 cm (impairing vision), or infantile hemangiomas involving lip(s) or oral cavity (impairing feeding).
- Ulceration can occur with profuse bleeding that can be life threatening.
- Disfigurement risk is increased with large (5 cm or larger) infantile hemangiomas, facial or scalp infantile hemangiomas, and breast infantile hemangiomas in female infants.
- An infantile hemangioma at least 2.5 cm in diameter overlying the lumbar spine or sacrum is an indication to do a spinal ultrasound (under 6 months of age) and/or MRI Lumbar Spine without contrast (CPT® 72148) or MRI Lumbar Spine without and with contrast (CPT® 72158).
- Infantile hemangiomas 5 cm or larger in size have an increased risk of extracutaneous structural abnormalities.
- Other high-risk indications include Syndromes or Associations with extracutaneous structural changes: for “PHACE(S) syndrome” See **Imaging Indications for PHACE(s) Syndrome**, and for “LUMBAR syndrome” See **Imaging Indications for LUMBAR Syndrome**.

Evidence Discussion

Infantile Hemangiomas are the most common benign tumor of childhood, occurring in close to 5% of infants. Infantile Hemangiomas typically have a phase of rapid and significant growth between 1 month and 3 months of age; growth is usually completed by 5 months of age. Gradual involution then occurs, completed in 90% by age of 4 years but with residual skin changes frequently persisting. Though usually not needed for diagnosis, biopsy can be done when needed to identify unique markers not found on other vascular tumors.

When treatment is needed, imaging may be used to monitor response; consultation with a hemangioma specialist may be useful in guiding evaluation, treatment, and follow-up. The 2019 Clinical Practice Guideline of the American Academy of Pediatrics states "Unlike many diseases, management of IHs is not limited to 1 medical or surgical specialty. A hemangioma specialist may have expertise in dermatology, hematology-oncology, pediatrics, facial plastic and reconstructive surgery, ophthalmology, otolaryngology, pediatric surgery, and/or plastic surgery, and his or her practice is often focused primarily or exclusively on the pediatric age group."

Multiple Infantile Hemangiomas (PEDPVD-5.2)

PVDP.IH.0005.2.A
v2.0.2026

- Multiple (5 or more) hemangiomas is an indication for Ultrasound with Doppler exam of the liver (CPT® 76700):
  - Initial imaging to look for hepatic hemangiomas
  - Repeat doppler ultrasound abdomen:
    - Monitor hepatic hemangiomas for progression
    - Monitor response to treatment.

Evidence Discussion

Multiple (5 or more) hemangiomas- though hepatic hemangiomas can be asymptomatic, they rarely can cause a high flow rate that can cause high-output cardiac failure and can be potentially fatal. "Diffuse" hepatic infantile hemangiomas are a rare subset of hepatic hemangiomas at high-risk for morbidity and mortality; affected infants usually present before 4 months of age with severe hepatomegaly, which can lead to lethal abdominal compartment syndrome with compromised ventilation, renal failure caused by renal vein compression, or compromise of inferior vena cava blood flow to the heart. Hepatic hemangiomas can also inactivate (via deiodination) thyroid hormones, causing risk of severe hypothyroidism.

PHACE(S) Syndrome (PEDPVD-5.3)

PVDP.IH.0005.3.A
v2.0.2026

Imaging Indications for PHACE(s) Syndrome

Initial Imaging

- Initial diagnostic imaging is medically necessary when PHACE(S) syndrome is suspected by clinical findings including **any** of the following:
  - Infantile hemangioma ≥5 cm diameter on the face, scalp, and/or neck.
  - Infantile hemangioma <5cm on face, scalp, or neck in the setting of one or more major anomalies associated with PHACE(S) syndrome (i.e., coarctation of the aorta or midline ventral defect).
  - Infantile hemangioma on upper chest or proximal upper extremity ≥5 cm with no visible facial infantile hemangioma with PHACE(S) syndrome in the setting of one or more major anomalies associated with PHACE(S) syndrome (i.e., coarctation of the aorta or midline ventral defect).
  - Large intraorbital infantile hemangioma.
- Initial imaging for suspected PHACE(S) syndrome includes **any** of the following:
  - MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553)
  - MRI Orbits without contrast (CPT® 70540) or MRI Orbits without and with contrast (CPT® 70543)
  - MRA Head without contrast (CPT® 70544) or MRA Head without and with contrast, (CPT® 70546)
  - MRA Neck may be done either without contrast (CPT® 70547), with contrast (CPT® 70548), or without and with contrast (CPT® 70549)
  - MRA Chest (CPT® 71555)
  - Transthoracic echocardiogram (CPT® 93303 with CPT® 93320 and CPT® 93325)
    - Cardiac MRI (CPT® 75557 or CPT® 75561) is medically necessary if abnormalities are identified on echocardiogram.
  - MRI Chest without contrast (CPT® 71550) or MRI Chest without and with contrast (CPT® 71552) is medically necessary if other clinical information or imaging shows involvement of the aorta.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Surveillance

Repeat imaging is medically necessary when results will impact clinical management of the individual based on the results of the initial clinical and imaging assessment and any subsequent clinical changes, or when high-risk findings have been identified by clinical evaluation such as any of the following:

- Evidence of past arterial stroke
- Arterial stenosis or occlusions, with or without moyamoya-like vascular changes
- Structural brain changes, with neurosurgical evaluation clarifying the need for follow-up.
- Changes in the aortic arch, coarctation of the aorta, and congenital cardiac anomalies, with pediatric cardiology evaluation clarifying the need for follow-up see **Imaging and Surveillance per Congenital Lesion (PEDCD-2.4)** in the Pediatric Cardiac Imaging Guidelines

Evidence Discussion

"PHACE" (Posterior fossa malformations, Hemangiomas, Arterial anomalies, Coarctation of the aorta and Cardiac defects, and Eye abnormalities) syndrome or association (or "PHACE(S)" syndrome when also associated with sternal cleft and/or supraumbilical raphe) is frequently suspected when an infant has a large (5 cm in diameter or larger) infantile hemangioma of the face, scalp, or neck (risk of PHACE(S) Syndrome is then approximately 30%).

In rare cases, the face or scalp is not involved, with a large infantile hemangioma located on the torso and/or upper extremity instead. Cerebrovascular anomalies, present in more than 90% of individuals with PHACE(S) syndrome, are the most common extracutaneous feature of the syndrome, followed by cardiac anomalies (67%) and structural brain anomalies (about 50%).

LUMBAR Syndrome (PEDPVD-5.4)

PVDP.IH.0005.4.A
v2.0.2026

Imaging Indications for LUMBAR Syndrome

- "LUMBAR syndrome" is reasonably suspected in a child with a large (5 or more cm in diameter) infantile hemangioma of any lumbosacral or perineal region or lower extremity. The following imaging is considered medically necessary:
  - Ultrasound spine (CPT® 76800) in infants up to 6 months of age, abdomen (CPT® 76700), and pelvis (CPT® 76856), with color Doppler.
  - MRI Lumbar Spine without contrast (CPT® 72148) or without and with contrast (CPT® 72158) at 3 to 6 months of age, or earlier when either findings on an Ultrasound exam are inadequate or when requested by a hemangioma specialist or any provider in consultation with a hemangioma specialist.
  - MRI of other relevant spinal level (relevance based on proximity of observed infantile hemangiomas larger than 5 cm) without contrast or MRI of the relevant spinal level without and with contrast.
  - When ultrasound findings are inadequate and/or when recommended by a hemangioma specialist or any provider in consultation with a hemangioma specialist:
    - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) **and/or**
    - MRI Abdomen without contrast (CPT® 74181) or without and with contrast (CPT® 74183).
  - MRA Abdomen CPT® 74185 and/or Pelvis CPT® 72198, is considered medically necessary based on proximity of infantile hemangioma(s) at least 5 cm in diameter and/or other clinical evidence of vascular involvement, and/or when recommended by a hemangioma specialist or any provider in consultation with a hemangioma specialist.
  - Infantile hemangioma of the lower extremity that is at least 5 cm in diameter is an indication for MRI of the relevant portion of the lower extremity without contrast (CPT® 73718) or lower extremity without and with contrast (CPT® 73720) and/or lower extremity joint without contrast (CPT® 73721) or lower extremity joint without and with contrast (CPT® 73723).
  - When there is extensive lower extremity involvement with infantile hemangiomas the following are all considered medically necessary:
    - MRA (for both arterial and venous phase imaging) Abdomen
    - MRA Pelvis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRA Lower extremities
- Note: this should be reported as CPT® 74185 and CPT® 73725; the CPT® code for MRA Pelvis (CPT® 72198) should not be included in this circumstance.

Evidence Discussion

The acronym "LUMBAR syndrome" refers to the association of lower body infantile hemangiomas of at least 5 cm in size (and other cutaneous defects), urogenital anomalies and ulceration, myelopathy (lipomyelocele/lipo-myelomeningocele and/or tethered spinal cord), bony deformities, anorectal malformations and arterial anomalies, and renal anomalies. Though not exclusively true, there is a general regional correlation between the location of the cutaneous large infantile hemangioma(s) with underlying structural anomalies.

General Guidelines (PEDSP-1.0)

SPP.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms, including a detailed history, physical examination with a thorough neurologic examination, appropriate laboratory studies and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MR, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) can serve as a pertinent clinical evaluation.
  - A thorough neurologic examination should include results of manual motor testing, specific dermatomal distribution of altered sensation, reflex examination, nerve root tension signs (e.g., straight leg raise test, slump test, femoral nerve tension test), and documentation of any specific radicular features.
- For those spinal conditions/disorders for which the Spine Imaging Guidelines require a plain x-ray of the spine prior to consideration of an advanced imaging study, the plain x-ray must be performed after the current episode of symptoms started or changed and results need to be available to the requesting provider of the advanced imaging study.
- Unless otherwise stated in a specific guideline section, the use of advanced imaging to screen asymptomatic individuals for disorders involving the spine is not supported. Advanced imaging of the spine should only be approved in individuals who have documented active clinical signs or symptoms of disease involving the spine.
- Unless otherwise stated in a specific guideline section, repeat imaging studies of the spine are not necessary unless there is evidence for progression of disease, new onset of disease, and/or documentation of how repeat imaging will affect individual management or treatment decisions.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Pediatric Spine Imaging Age Considerations (PEDSP-1.1)

SPP.GG.0001.1.A

v1.0.2026

- Many conditions affecting the spine in the pediatric population have different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, minor differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.
- Individuals who are ≤18 years old should be imaged according to the Pediatric Spine Imaging Guidelines if discussed. Any conditions not specifically discussed in the Pediatric Spine Imaging Guidelines should be imaged according to the General Spine Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Spine Imaging Guidelines, except where directed otherwise by a specific guideline section.

Pediatric Spine Imaging Modality General Considerations (PEDSP-1.3)

SPP.GG.0001.3.A
v1.0.2026

- MRI
  - MRI is the preferred modality for imaging the pediatric spine unless otherwise stated in a specific guideline section.
  - Due to the length of time required for MRI acquisition and the need to minimize individual movement, anesthesia is usually required for almost all infants (except neonates) and young children (age <7 years), as well as older children with delays in development or maturity. This anesthesia may be administered via oral or intravenous routes. In this individual population, MRI sessions should be planned with a goal of minimizing anesthesia exposure by adhering to the following considerations:
    - MRI procedures can be performed without and/or with contrast use as supported by these condition based guidelines. If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may be appropriate if requested. By doing so, the requesting provider may avoid repetitive anesthesia administration to perform an MRI with contrast if the initial study without contrast is inconclusive.
    - Recent evidence-based literature demonstrates the potential for gadolinium deposition in various organs including the brain, after the use of MRI contrast.
      - The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting gadolinium-based contrast agents (GBCAs) use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
    - If multiple body areas are supported by these guidelines for the clinical condition being evaluated, MRI of all necessary body areas should be obtained concurrently in the same anesthesia session.
- CT
  - CT is generally inferior to MRI for imaging the pediatric spine, but has specific indications in which it is the preferred modality listed in specific sections of these guidelines.
    - CT is the imaging study of choice in the setting of trauma

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - CT should not be used to replace MRI in an attempt to avoid sedation unless it is listed as a recommended study in a specific guideline section.
    - Myelogram with post-myelogram CT imaging is rarely indicated in children except in certain limited indications (usually requested after specialist consultation), including:
        - Evaluation of spine in individuals with fixation hardware which limits utility of MRI.
        - Severe congenital scoliosis with inconclusive MRI.
        - Evaluation of nerve root avulsion in patients with a brachial plexus injury and inconclusive MRI.
        - Evaluation of paraspinal cyst to assess continuity with the subarachnoid space.
        - Coding note: CT of appropriate spinal level with or without contrast may be appropriate. If the radiologist performs the myelogram the exam should be coded with contrast. If a clinician performs the myelogram the exam should be coded without contrast.
- Ultrasound
    - Spinal canal ultrasound (CPT® 76800) describes the ultrasonic evaluation of the spinal cord (canal and contents) and should not be reported multiple times for imaging of different areas of the spinal canal.
    - Do not use CPT® 76800 for intraoperative spinal canal ultrasound as CPT® 76998 (intraoperative ultrasonic guidance) is the appropriate code in this circumstance.
    - Spinal canal ultrasound (CPT® 76800) is generally limited to infants up to 6 months of age because of the bone mass surrounding the spinal cord limits evaluation of the intraspinal contents in older infants.
        - **Exception:** the persisting acoustic window in children with posterior spinal defects of spinal dysraphism enables spinal canal ultrasound to be performed at any age (see: **Spinal Dysraphism (PEDSP-4)**).
        - In general, additional imaging studies of the spine are not indicated in asymptomatic individuals with normal spinal ultrasound findings.
- Nuclear Medicine
    - Nuclear medicine studies are rarely used in the evaluation of the spine, but are medically necessary in the following circumstances:
        - Evaluation of suspected loosening of orthopedic hardware when recent plain x-ray is nondiagnostic (see: **Nuclear Medicine (MS-28)**).
            - Bone scan (CPT® 78315) or
            - Distribution Of Radiopharmaceutical Agent SPECT (CPT® 78803, or 78831) or
            - SPECT/CT (CPT® 78830 or CPT® 78832)
        - For suspected spondylolysis, see **Spondylosis (PEDSP-2.4)**

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Evaluation of back pain when no cause is demonstrated on MRI, see **Back and Neck Pain in Children Age 5 and Under (PEDSP-2.2)** or **Back and Neck Pain in Children Age 6 and Older (PEDSP-2.3)**
- The guidelines listed in this section for certain specific indications are not intended to be all-inclusive; clinical judgment remains paramount and variance from these guidelines may be appropriate and warranted for specific clinical situations.

Introduction (PEDSP-2.1)

SPP.TR.0002.1.A

v1.0.2026

- Currently, only about 20% of back pain in children over age 5 is from a discoverable cause. Scoliosis, spondylitic disorders, Scheuermann disease, tumor, and trauma are the most common causes.
- Back pain in children under age 5 is uncommon and often reflects underlying serious disease when present.
- Disc herniations are rare in children, but become more frequent as activity increases during adolescence.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Back and Neck Pain in Children Age 5 and Under (PEDSP-2.2)

- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, and plain radiography should be performed prior to considering advanced imaging.
- Advanced imaging is medically necessary in all individuals in this age group except those with mild and transient back pain.
  - MRI of the symptomatic spinal region is medically necessary.
    - Individuals in this age group will require sedation to complete MRI imaging. See: **Pediatric Spine Imaging Modality General Considerations (PEDSP-1.3)** for contrast and body area considerations.
  - CT without contrast of the symptomatic spinal region is medically necessary when:
    - plain x-rays suggest an isolated vertebral bone abnormality without any concern for spinal canal or cord abnormalities (which is rare in this age group)
    - a recent MRI does not provide sufficient detail of the bony anatomy to allow for acute patient care decision making
  - Bone scan is medically necessary for evaluation of suspected spinal fracture when x-ray is negative using any of the following CPT® code combinations:
    - CPT® 78300, CPT® 78305, or CPT® 78306 as a single study
    - CPT® 78315 or CPT® 78803 can be approved as a single study when stress fracture is suspected.
  - Bone scan is medically necessary for evaluation of suspected spondylolysis, or if recent spine MRI is inconclusive using any of the following CPT code combinations: SPECT bone scans are especially sensitive for detecting spondylolysis, revealing areas of bone turnover; and the findings are generally positive for a prolonged period.
    - CPT® codes: CPT® 78300, CPT® 78305, CPT® 78306, CPT® 78315, or CPT® 78803 as a single study
    - CPT® 78305 and CPT® 78803 concurrently
    - CPT® 78306 and CPT® 78803 concurrently

Back and Neck Pain in Children Age 6 and Older (PEDSP-2.3)

SPP.TR.0002.3.A
v1.0.2026

Radicular back and neck pain is common in adult patients but is uncommon in adolescents and rare in children.

- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination including results of manual motor testing, the specific dermatomal distribution of altered sensation, reflex examination, and nerve root tension signs (e.g., straight leg raise test, slump test, femoral nerve tension test) and documentation of any specific radicular features, should be performed prior to considering advanced imaging.
- X-rays, while not required prior to conservative treatment, must be obtained before advanced imaging can be approved.
  - The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider of the advanced imaging study.
- Advanced imaging is medically necessary following x-ray when one or more of the following pediatric “red flags” are present:
  - Accompanying systemic symptoms (fever, weight loss, etc.)
  - Functional disability (daily limitation in normal activities because of pain)
  - Pain which is extremely severe or worse at night
  - Constant or radicular pain lasting ≥4 weeks
  - Pain which worsens despite an attempt at symptomatic treatment
  - Neurological symptoms or abnormal neurological examination findings
  - An established diagnosis of cancer other than leukemia
  - Abnormal x-rays
  - Individuals having undergone spinal surgery
  - Associated bowel or bladder dysfunction
- In the absence of any “red flags”, a 4-week trial of provider-supervised conservative treatment (after the current set of symptoms or physical exam findings started or changed) should be attempted before advanced imaging is medically necessary.
  - It can be assumed that children who are being evaluated by a pediatric spine surgeon have failed a reasonable trial of conservative treatment under the care of the primary care provider, as this is by far the most common reason for such referrals.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- X-rays of the involved regions should be obtained prior to advanced imaging in individuals with “red flag” findings, or who remain symptomatic after a 4-week trial of provider-supervised conservative treatment.
  - The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider of the advanced imaging study.
- MRI without contrast of the symptomatic spinal region is medically necessary for the evaluation of pediatric spine pain, and should be approved unless one of the following conditions applies, in which case MRI without and with contrast is medically necessary:
  - Fever (≥100° F)
  - Clinical suspicion of infection (discitis, osteomyelitis, paraspinous or epidural abscess)
  - Physical examination or plain x-ray suggests a mass lesion
  - New or worsening pain in a patient with an established diagnosis of cancer
- CT without contrast of the symptomatic spinal region is medically necessary when:
  - the request is for re-evaluation of a known vertebral bony disorder
  - plain x-rays show spondylotic changes or suggest an isolated vertebral bone abnormality without any concern for spinal canal or cord abnormalities (which is rare in this age group)
  - a recent MRI does not provide sufficient detail of the bony anatomy to allow for acute individual care decision making
- Bone scan is medically necessary for evaluation of suspected spinal fracture when x-ray is negative, or if recent MRI is inconclusive using any of the following CPT® code combinations:
  - CPT® codes: CPT® 78300, CPT® 78305, or CPT® 78306 as a single study
  - CPT® 78315 or CPT® 78803 as a single study when stress fracture is suspected

Click Here to Return to the Main TOC

Spondylolysis (PEDSP-2.4)

SPP.TR.0002.4.A
v1.0.2026

Most cases of childhood spondylolysis are believed to be caused by repeated microtrauma, resulting in stress fracture of the pars interarticularis. Heredity is also believed to be a factor in some cases. It is the most common cause of low back pain in children older than age 10.

- Activity modification, NSAID treatment, physical therapy, and/or immobilization with various braces are the initial treatments for symptomatic individuals.
- Surgical treatment is only recommended for individuals with disabling symptoms that have not responded to non-surgical care.
- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, and plain radiography should be performed prior to considering advanced imaging.
- Spondylolysis is screened with plain x-rays.
  - MRI without contrast of the symptomatic spinal level is medically necessary to evaluate for stress reaction in bone and visualizing nerve roots if symptoms have continued despite a provider-directed 4-week course of conservative care after the current set of symptoms or physical exam findings started or changed, or if there is a documented need for preoperative planning.
  - If additional imaging is needed because of radiological uncertainty or associated spondylolisthesis, SPECT Radiopharmaceutical Localization Imaging (CPT® 78803) or SPECT/CT (CPT® 78830) is medically necessary to identify stress reaction in spondylolysis cases which are radiographically occult. Bone scan has been demonstrated to be superior to MRI in detecting active spondylolysis.
  - SPECT bone scans are especially sensitive for detecting spondylolysis, revealing areas of bone turnover; and the findings are generally positive for a prolonged period. CT without contrast of the symptomatic spinal level is medically necessary to provide detailed evaluation of bony anatomy, if there is a documented need for preoperative planning. CT scans have been considered the criterion standard for characterizing fractures and for detailing bone morphology and anatomy.

Click Here to Return to the Main TOC

Spine Pain Due to Infectious Causes (PEDSP-2.5)

- Entities including, but not limited to, discitis and vertebral osteomyelitis, typically present with sudden onset of back pain, fever, and elevated white blood cell count, occurring most commonly in the first decade of life.
- A detailed history and physical examination with thorough neurologic examination should be performed initially.

Initial Imaging Studies

- Plain x-rays should be performed initially.
  - The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider of the advanced imaging study.
- MRI without and with contrast of the symptomatic spinal level is very sensitive at detecting early changes and is medically necessary when discitis or osteomyelitis is clinically suspected.
- Nuclear medicine imaging also can be positive as soon as 1 to 2 days after the onset of symptoms. Any of the following studies are medically necessary for initial evaluation of suspected osteomyelitis:
  - Bone scan (one of CPT® codes: CPT® 78300, 78305, 78306, or 78315)
  - Nuclear Bone Marrow imaging (one of CPT® codes: CPT® 78102, 78103, or 78104)
  - Radiopharmaceutical inflammatory imaging (one of CPT® codes: CPT® 78800, 78801, 78802, 78803, or 78804)
  - SPECT (CPT® 78831)
  - SPECT/CT (CPT® 78830, or CPT® 78832)

Follow-Up Imaging Studies

- Follow-up plain x-rays may show disc space narrowing and bony changes of osteomyelitis.
- MRI without and with contrast of the symptomatic spinal level or CT with contrast (including myelography) is medically necessary for follow-up evaluating bony changes of osteomyelitis or concern for epidural abscess.
- Any of the following studies are medically necessary for evaluation of response to treatment in established osteomyelitis:
  - Bone scan (one of CPT® codes: CPT® 78300, 78305, 78306, or 78315)

Proprietary Information of UnitedHealthcare.

Spine Pain Related To Trauma and Painless Spine Trauma (PEDSP-2.6)

SPP.TR.0002.6.A

v1.0.2026

- Imaging evaluation of traumatic spine injury in children is generally directed based on clinical examination. 60% to 80% of all spinal injuries in children involve the cervical spine as opposed to the thoracic spine and lumbar spine. Common causes are motor vehicle accidents, falls, and sports-related injuries.
- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, should be performed prior to considering advanced imaging.
- When advanced imaging is appropriate, MRI without contrast or CT without contrast of the involved level is medically necessary as discussed in **Pediatric Spine Imaging Modality General Considerations (PEDSP-1.3)**
  - If the initial CT or MRI study is considered inconclusive, an exam of the other modality is medically necessary if needed to direct clinical management.

Cervical Spine

- The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider of the advanced imaging study
- Advanced imaging of the cervical spine is medically necessary in children under 3 years of age following a relevant x-ray when one or more of the following “red flags” are present:
  - Glasgow Coma Scale <14
  - Individual does not open eyes regardless of stimulus
  - Motor vehicle collision
- Advanced imaging of the cervical spine is medically necessary in children ≥3 years of age following a relevant x-ray when one or more of the following “red flags” are present:
  - Altered mental status
  - Focal neurologic findings
  - Neck pain
  - Torticollis not present prior to trauma
  - Substantial torso injury
  - Diving or head-first injury
  - High speed motor vehicle collision
  - Predisposing conditions, e.g., Down syndrome

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Advanced imaging of the cervical spine is not medically necessary in children older than 2 years of age if they meet ALL of the following criteria:
  - Absence of posterior midline cervical pain
  - Absence of focal neurologic deficit
  - Normal level of alertness
  - No evidence of intoxication
  - Absence of other clinically apparent pain which could distract patient from the pain of a cervical injury

Thoracolumbar Spine

- Advanced imaging of the thoracolumbar spine is medically necessary in children following a recent x-ray when x-rays are inconclusive, or there is an abnormal neurological examination.

Suspected Physical Child Abuse

- In children with suspected physical child abuse and documented findings suggesting abuse (e.g., fractures on skeletal survey or other clinical indicators), MRI Cervical (CPT® 72141), Thoracic (CPT® 72146), and Lumbar (CPT® 72148) Spine without contrast are medically necessary to search for associated abnormalities.
  - If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast is medically necessary. See: **Pediatric Spine Imaging Modality General Considerations (PEDSP-1.3)**

Juvenile Thoracic Kyphosis (Scheuermann Disease) (PEDSP-3.1)

SPP.KS.0003.1.A

v1.0.2026

- This condition is also known as Scheuermann Kyphosis, and these individuals generally present with chronic and recurrent back pain.
- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, and plain radiography should be performed prior to considering advanced imaging.
- X-rays will typically show anterior wedging in three or more adjacent vertebral bodies.
  - Lower thoracic kyphosis from developmental vertebral wedging with thoracic kyphosis varying between 20° and 45° should be identified by plain x-rays before considering advanced imaging.
  - MRI is not an effective diagnostic modality and is therefore not medically necessary for this condition since the incidence of false positive vertebral changes in normal individuals is high.
- MRI Thoracic Spine without contrast (CPT® 72146) is medically necessary preoperatively to rule out any associated spinal cord problems.
- MRI Lumbar Spine without contrast (CPT® 72148) is medically necessary preoperatively to rule out any associated spinal cord conditions when there is clinical or radiographic evidence of lumbar abnormalities.

Scoliosis (PEDSP-3.2)

SPP.KS.0003.2.A

v1.0.2026

- Scoliosis is an abnormal lateral curve of the thoracic or thoraco-lumbar spine in the frontal plane. A small lateral curve in a skeletally mature person is not uncommon and generally does not require further investigation.
- Using the Cobb technique for measuring these curves, a curve of under 10˚ is normal, a curve from 10˚ to 20˚ is mildly abnormal, a curve over 20˚ is significantly abnormal, and a curve over 40˚ is severely abnormal.
- Most individual with significant scoliosis have some element of kyphosis as well.
  - There are many ways of classifying scoliosis. These guidelines will classify scoliosis as congenital, idiopathic, and neuromuscular scoliosis.
- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, detailed examination of the spine in different body positions, and plain radiography should be performed prior to considering advanced imaging.
  - Standing posteroanterior (PA) and lateral x-rays of the spine are the initial imaging studies and are used for follow-up. If anteroposterior (AP) x-rays are to be performed, breast shields should be used to reduce breast radiation exposure.
  - Spine surgical specialists sometimes appropriately request both MRI and CT together for preoperative planning of scoliosis surgery.
    - In addition, MR and CT are useful to identify an underlying cause of scoliosis, such as congenital and developmental anomalies.
    - MR or CT Spine is medically necessary postoperatively when recent postoperative x-rays are inconclusive for managing individual treatment.
      - Individuals with severe scoliosis may have compromised lung development. CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) is medically necessary in the perioperative period as well as 2 and 5 years postoperatively to assess lung growth.

Congenital Scoliosis

Cases are recognized in infancy or early childhood. Most cases arise from anomalies of vertebral development, and many are associated with anomalies of the genitourinary system or of other organs.

- In infants under 6 months of age spinal ultrasound (CPT® 76800) is medically necessary after initial imaging with plain x-rays.
- MRI Cervical (CPT® 72141), Thoracic (CPT® 72146), and Lumbar (CPT® 72148) Spine without contrast are medically necessary to search for underlying anomalies.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - If intravenous access will already be present for anesthesia administration and there is no contraindication for using contrast, imaging without and with contrast may, is medically necessary. See: **Pediatric Spine Imaging Modality General Considerations (PEDSP-1.3)**
- MRI Brain without and with contrast is medically necessary if the clinical evaluation or preliminary imaging studies suggest an associated intracranial anomaly.
- Renal ultrasound (CPT® 76770 or CPT® 76775) is medically necessary since nearly one-third of individuals also have genitourinary anomalies.
  - CT, MRI, or nuclear medicine studies of the genitourinary tract are medically necessary if the ultrasound is abnormal.

Idiopathic Scoliosis

Idiopathic scoliosis is the most common form of pediatric scoliosis and is divided into infantile (0-3 years of age), juvenile (4-9 years of age), and adolescent (10-17 years of age). Idiopathic scoliosis is defined as having no underlying structural abnormality or accompanying syndrome.

- The following clinical features are associated with an increased risk of underlying vertebral or spinal cord abnormality:
  - Associated back pain
  - Age younger than 10 years
  - Neurological abnormalities on examination or neurological symptoms
  - Left sided curve (concave to right)
  - Absence of apical segment lordosis/kyphosis
  - Rapid curve progression (>1 degree per month)
  - Pes Cavus (see: **Occult Spinal Dysraphism (PEDSP-4.3)**
  - Double curves or high thoracic curves
  - Kyphosis
  - Spinal x-ray abnormalities other than the curve itself (widened spinal canal, dysplastic changes in spine or ribs, etc.)
  - Midline spinal cutaneous markers (esp. sacral) such as dermal tracts, tufts of hair, skin tags, etc.
  - Abnormal number or size of café au lait spots (neurofibromatosis)
- MRI Cervical (CPT® 72141), Thoracic (CPT® 72146), and Lumbar (CPT® 72148) Spine without contrast are the medically necessary studies for the evaluation of scoliosis when any of the above clinical features is present or if imaging is requested for individuals who are being actively evaluated for corrective surgery.

Neuromuscular Scoliosis

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Scoliosis can result from many disorders of the nervous system. In some conditions, including (but not limited to) cerebral palsy, muscular dystrophy, and spinal muscular atrophy, associated scoliosis may develop over time.

The appropriate spinal level, modality, and contrast level of advanced imaging will depend on the nature of the underlying disease.

- MRI without contrast or without and with contrast or CT without contrast of the cervical, thoracic, and/or lumbar spine is medically necessary in these individuals with painful neuromuscular scoliosis, or when they are actively being evaluated for spinal deformity corrective surgery.
- Bone scans (one of CPT® codes: CPT® 78300, CPT® 78305, CPT® 78306, or CPT® 78315) are medically necessary to evaluate cases of painful scoliosis and to identify tumors or infections. They are more sensitive than plain radiography.
  - Post-surgical considerations are similar to adult post-operative indications (see: **Post-Operative Spinal Disorders (SP-15)** in the General Spine Imaging Guidelines) except as follows:
    - Post-operative CT Chest without contrast (CPT® 71250) with 3D reconstruction is medically necessary for lung volume measurement in children with early onset scoliosis, (e.g., congenital/thoracogenic type), due to risk of restrictive lung disease and thoracic insufficiency syndrome which occur from failure of spine and chest to support normal lung growth.

Introduction (PEDSP-4.1)

SPP.TC.0004.1.A
v1.0.2026

Spinal Dysraphism

- Spinal dysraphism refers to a group of disorders characterized by incomplete or absent fusion of posterior midline structures. This includes a range of congenital and/or developmental anomalies of the spinal cord and associated spinal structures that can affect any level of the spine, but most commonly the lumbosacral region.
- Based on clinical classification, dysraphism is grouped into two categories:
  - Open dysraphism (spina bifida aperta), which are non-skin-covered, open neural tube defects (myelomeningocele).
  - Occult spinal dysraphism (also called closed spinal dysraphism), which includes skin-covered defects (either with or without an associated subcutaneous mass).

Normal position of spinal cord

- In newborns, the spinal cord should terminate (at the conus medullaris) at L2-3 or higher.
- By 3 months of age, the conus should lie at or above the L2 level.
- Afterwards, in normal infants and children, the conus medullaris should be positioned at L1-2.
- Of note, however, in premature infants, the conus medullaris may be located at the mid L3-level.
  - If such a finding on an initial spinal ultrasound results in uncertainty as to whether cord termination is low, repeat spinal ultrasound (CPT® 76800) is medically necessary in 4 to 6 weeks, since a normal cord will have “moved” higher within the spinal canal by this time.

Tethered cord

- Tethering is certain when the cord terminates at or below L4 and there is other supporting evidence of tethering such as limited spinal cord pulsatility, posterior positioning in the spinal canal, thick filum terminale, intraspinous mass, or lipoma.
- If the conus terminates at a normal position (at L2-3 under 3 months of age, at L2 by 3 months of age, at L1-2 in older infants and children), the cord may still be tethered by an abnormal structure. Such tethering of the spinal cord can be found in some (but not all) individuals with occult spinal dysraphism. Abnormalities can be found in both lumbosacral and thoracic regions and are often associated with spinal lipomas in either region.
- Open spinal dysraphism is frequently associated with tethering of the spinal cord; symptoms of or findings from that tethering may manifest initially or may increase

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

after the newborn period and the initial imaging evaluation. See: **Open Dysraphism (PEDSP-4.4)**.

"Tethered cord Syndrome"

- "Tethered Cord Syndrome" refers to symptoms and abnormal physical findings (such as low back or leg pain, decreased or absent lower extremity reflexes, urinary urgency, urinary incontinence, bowel incontinence, and constipation) that arise when a pathologic attachment causes abnormal spinal tension (increased by axial growth), with ensuing pathophysiologic effects. Some of these patients do have an abnormally low conus medullaris; other patients have other spinal abnormalities (such as spinal dysraphism) that causes the spinal cord to be abnormally tethered. Other patients with spinal dysraphism who may present with symptoms or findings suggestive of "Tethered Cord Syndrome" may have those clinical manifestations caused by primary dysplasia of neural tissue, instead of being caused by abnormal tethering. See: **Non-Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.3)**.
- Not all anatomically tethered spinal cords result in symptoms of "Tethered Cord Syndrome."

Imaging Studies to Evaluate Suspected Occult Spinal Dysraphism and/or Tethered Cord

- Plain x-rays are not indicated for suspected occult spinal dysraphism and/or tethered cord.
- Spina bifida occulta, an incomplete fusion of the posterior lumbosacral bony elements (present in in about 25% of people), is often discovered as an incidental finding on x-rays and other imaging exams. In asymptomatic individuals it is of no consequence, and is not an indication for further imaging.
- A plain spine x-ray finding suggesting an absent or distorted pedicle (the "winking owl sign") can be indicative of occult spinal dysraphism, for which an initial MRI without contrast or MRI without and with contrast of the appropriate spinal level is medically necessary.
- When indicated (See: **Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.2)**, **Non-Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.3)**, and **Open Dysraphism (PEDSP-4.4)** for indications), the following imaging is medically necessary:
  - Spinal ultrasound (CPT® 76800) for initial evaluation in infants up to 6 months of age, in premature infants whose "corrected age" (subtracting the number of weeks of prematurity from the infant's actual age) is less than or equal to 6 months, or in older individuals with open spinal dysraphism (see: **Open Dysraphism (PEDSP-4.4)**).
  - In a term infant, the diagnosis of tethered cord is likely if the conus terminates below the L2-L3 disc space. Of note, however, in premature infants, the conus medullaris may be located at the mid L3-level; if there is uncertainty as to whether

Proprietary Information of UnitedHealthcare.

cord termination is low in a premature infant, repeat spinal ultrasound (CPT® 76800) is medically necessary in 4 to 6 weeks, since a normal cord will have "moved" higher within the spinal canal by this time.

- MRI Cervical, Thoracic, and Lumbar spine without contrast (CPT® 72141, 72146, and 72148) or without and with contrast (CPT® 72156, 72157, and 72158) is medically necessary for initial evaluation in individuals older than 6 months of age.
  - MRI is medically necessary at a younger age when there are symptoms or physical findings or concerning findings on ultrasound showing the need for more prompt MRI imaging, or when MRI imaging prior to 6 months of age has been ordered by (or in consultation with) an appropriate specialist for an indication from **Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.2)**, **Non-Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.3)**, or **Open Dysraphism (PEDSP-4.4)**.
- The appropriate spinal level, modality, and contrast level of follow-up advanced imaging will depend on the nature of the underlying disease, usually ordered by (or after consultation with) an appropriate specialist.
- Postoperative MRI is not done routinely but is medically necessary if there are recurrent symptoms or findings suggesting recurrent tethering or other deterioration. Contrast level per ordering specialist.
- A complete abdominal ultrasound (CPT® 76700) or retroperitoneal ultrasound (CPT® 76770) is medically necessary as an initial evaluation for patients with newly diagnosed neurogenic bladder, myelomeningocele (open spinal dysraphism), or occult spinal dysraphism.
  - A complete retroperitoneal ultrasound (CPT® 76770) is medically necessary every 6 to 12 months for follow-up/surveillance for any of the above conditions.
- CT of the effected spinal level is medically necessary for surgical planning when a complex bony deformity of the spine is present, or when the Guidelines support doing MRI of the spine in an individual for whom MRI is contraindicated.

Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.2)

SPP.TC.0004.2.A
v1.0.2026

- More than 80% of individuals with occult spinal dysraphism and/or tethered spinal cord will have a cutaneous lesion overlying the lower spine.
- Spine imaging is not medically necessary in the following situations:
  - Pilonidal cysts below the level of the intergluteal fold.
    - For discussion of imaging in pilonidal cysts, see: **Pilonidal Cyst (PV-21.4)** in the Pelvis Imaging Guidelines
  - Non-specific darkened areas of skin over the sacrum (such as dermal melanosis) unless there are other associated midline cutaneous abnormalities
  - Occult bony dysraphism incidentally noted on x-ray
- Screening with advanced imaging is medically necessary in the following clinical conditions which are associated with an increased risk of underlying spinal dysraphism:
  - Spinal dimples (midline soft tissue depression over the spine); or deviated or split (bifid) gluteal cleft
    - Spinal ultrasound (CPT® 76800) is medically necessary for initial evaluation in infants up to 6 months of age (or in premature infants with a “corrected” age up to 6 months of age). Follow-up of a normal screening spinal ultrasound with ultrasound is not medically necessary.
    - MRI of the involved spinal level without contrast or without and with contrast is medically necessary for initial evaluation in individuals older than 6 months of age. MRI is medically necessary at a younger age when there are symptoms or physical findings or concerning findings on ultrasound showing the need for more prompt MRI imaging, or if ordered by (or in consultation with) an appropriate specialist.
    - A screening MRI is medically necessary after a normal screening spinal ultrasound exam. Follow-up of a normal screening MRI imaging study is not medically necessary.
  - Dermal sinuses overlying the lumbar, thoracic, or cervical spine, and sacral dermal sinuses, whether manifested by a dermal sinus tract (a small opening in the skin, which leads into a narrow duct; it may be associated with protruding hairs) or a dermal cyst. They may be associated with an overlying or nearby hairy patch or vascular nevus
    - Spinal ultrasound (CPT® 76800) is medically necessary for initial evaluation in infants up to 6 months of age (or in premature infants with a “corrected” age up

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

to 6 months of age). Follow-up of a normal screening spinal ultrasound is not medically necessary.
    - MRI of the involved spinal level without contrast or without and with contrast is medically necessary if an ultrasound shows abnormalities other than a cutaneous dermal cleft, if ordered after 6 months of age, or at a younger age if ordered by (or in consultation with) an appropriate specialist.
    - A screening MRI is medically necessary after a normal screening spinal ultrasound exam. Follow-up of a normal screening MRI imaging study is not medically necessary.
- Subcutaneous midline masses (including cysts and lipomas) at any level.
    - Plain x-rays are not required to approve other imaging for midline masses overlying the spine when occult spinal dysraphism and/or tethered cord is suspected.
    - Spinal ultrasound (CPT® 76800) is medically necessary for initial evaluation in infants up to 6 months of age (or in premature infants with a “corrected” age up to 6 months of age), but MRI of the involved spinal level without contrast or without and with contrast is the preferred medically necessary initial imaging for midline masses overlying the spine. Repeat ultrasound follow-up of a normal screening spinal ultrasound is not medically necessary.
    - MRI of the involved spinal level without contrast or without and with contrast is medically necessary for initial evaluation in patients older than 6 months of age. MRI is medically necessary at a younger age when there are symptoms or physical findings or concerning findings on ultrasound showing the need for more prompt MRI imaging, or if ordered by (or in consultation with) an appropriate specialist.
    - A screening MRI is medically necessary after a normal screening spinal ultrasound exam. Follow-up of a normal screening MRI imaging study is not medically necessary.
- Caudal extensions (including tail-like appendages), midline skin tags, abnormal patches of hair over the spine at any level, infantile hemangiomas overlying any spinal level, and complex midline birthmarks above the upper sacral region.
    - Spinal ultrasound (CPT® 76800) is medically necessary for initial evaluation in infants up to 6 months of age (or in premature infants with a “corrected” age up to 6 months of age). Repeat ultrasound follow-up of a normal screening spinal ultrasound is not medically necessary.
    - MRI of the involved spinal level without contrast or without and with contrast is medically necessary for initial evaluation in individuals older than 6 months of age. MRI is medically necessary at a younger age when there are symptoms or physical findings or concerning findings on ultrasound showing the need for more prompt MRI imaging, or if ordered by (or in consultation with) an appropriate specialist.

Non-Cutaneous Indications to Suspect Occult Spinal Dysraphism (PEDSP-4.3)

SPP.TC.0004.3.A
v1.0.2026

- Imperforate anus
- VACTERL (vertebral malformations, anal atresia, cardiac anomalies, tracheo-esophageal fistula, renal abnormalities, and limb defects) syndrome
- Currarino triad (sacral dysgenesis, presacral mass, anorectal malformation), OEIS (omphalocele, exstrophy, imperforate anus, spinal defects) syndrome
- Caudal regression syndrome
- Sacral agenesis (when 2 or more of the sacral vertebral bodies are absent; about 20% of children with sacral agenesis are not detected prior to age of 3 years).
- For all of the above conditions, the following imaging is medically necessary:
  - Spinal ultrasound (CPT® 76800) for initial evaluation in infants up to 6 months of age (or in premature infants with a “corrected” age up to 6 months of age). Repeat ultrasound follow-up of a normal screening spinal ultrasound is not medically necessary.
  - MRI Lumbar Spine without contrast (CPT® 72148) or without and with contrast (CPT® 72158); and/or MRI Pelvis without contrast (CPT® 72195) or MRI Pelvis without and with contrast (CPT® 72197).
  - Appropriate MRI (or other modality) imaging (including contrast level) of any other spinal level will depend on the nature of the underlying disease, usually ordered by (or in consultation with) an appropriate specialist.
  - Follow-up of a normal screening MRI imaging study is not medically necessary, but an initial MRI can be approved if the first screening study was an ultrasound.
  - Postoperative MRI is not done routinely but is medically necessary if there are recurrent symptoms or findings suggesting recurrent tethering. Contrast level per ordering specialist.
- For Rubinstein-Taybi syndrome (gait abnormalities, short stature, short limbs, characteristic facies, developmental delay, tethered spinal cord), the following imaging is medically necessary:
  - Spinal ultrasound (CPT® 76800) for initial evaluation in infants up to 6 months of age (or in premature infants with a “corrected” age up to 6 months of age). Repeat ultrasound follow-up of a normal screening spinal ultrasound is not medically necessary.
  - MRI Lumbar spine without contrast (CPT® 72148) or without and with contrast (CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Appropriate MRI (or other modality) imaging (including contrast level) of any other spinal level will depend on the nature of the underlying disease, usually ordered by (or in consultation with) an appropriate specialist.
- Follow-up of a normal screening MRI imaging study is not medically necessary, but an initial MRI can be approved if the first screening study was an ultrasound.

- For individuals with known DiGeorge Syndrome (22q11.2 deletion syndrome), the following imaging is medically necessary when tethered cord syndrome or occult spinal dysraphism is suspected:
  - Spinal ultrasound (CPT® 76800) for initial evaluation in infants up to 6 months of age
  - MRI Lumbar Spine without contrast (CPT® 72148) or without and with contrast (CPT® 72158)
  - Appropriate MRI (or other modality) imaging (including contrast level) of any other spinal level will depend on the nature of the underlying disease, usually ordered by (or in consultation with) an appropriate specialist.
  - Follow-up of a normal screening MRI imaging study is not medically necessary, but an initial MRI can be approved if the first screening study was an ultrasound.
- MRI of the involved spinal level without contrast or without and with contrast is medically necessary for neurologic related symptoms and physical exam findings suggestive of occult spinal dysraphism, tethered cord syndrome, and/or low lying conus medullaris when any of the following are present:
  - Asymmetry of the feet, with one smaller foot, a high arch, and/or clawing of the toes. This is sometimes called the “neuroorthopedic syndrome”, and is associated with lack of an ipsilateral ankle jerk deep tendon reflex and calf atrophy.
  - Cavus foot (also called pes cavus or pes cavovarus)
  - Toe walking, when associated with upper motor neuron signs including hyperreflexia, spasticity, and positive Babinski sign
  - Ataxia (see: **Ataxia (PEDHD-20)**)
  - Absent perineal sensation
  - Lower urinary tract dysfunction, including urinary urgency or urinary incontinence. Though not a requirement for advanced imaging, some of these patients will have had abnormal urodynamic studies (such as cystometrography and/or sphincter electromyography).
  - Constipation, especially if there are abnormal physical exam findings related to the spine (such as lower extremity weakness, decreased lower extremity tone, abnormal lower extremity reflexes, a tuft of hair over the spine or covering a pilonidal dimple, a sacral dimple, gluteal cleft deviation, or absent anal or cremasteric reflex), failure of maximal laxative therapy (see: **Constipation, Diarrhea, and Irritable Bowel Syndrome (PEDAB-12)**) and/or bowel incontinence, when tethered cord syndrome or occult spinal dysraphism is suspected as the cause

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Back or leg pain when tethered cord syndrome or occult spinal dysraphism is suspected as the cause. In this setting, neither a plain x-ray of the spine nor a recent period of provider directed conservative treatment is required to approve an MRI spine).
- See: **Myelopathy (SP-7.1)**, **Myelopathy (PEDSP-6)**, and **Developmental Motor Delay (PEDHD-19.3)** for spinal cord involvement suspected in individuals with developmental motor delay.

Spinal Dysraphism (PEDSP-4.4)

SPP.TC.0004.4.A

v1.0.2026

- Clinically significant dysraphism includes findings ranging from complex vertebral anomalies to myelomeningocele.
- Dysraphism is categorized into 2 major groups:
  - Open Dysraphism - lack of skin covering with exposed neural elements
  - Closed Dysraphism - skin covered
- It is rare to perform MRI in neonates with open dysraphism as the diagnosis is usually made with obstetric ultrasound and confirmed with visual inspection
  - MRI of the entire spine is medically necessary for preoperative planning if ordered by a specialist.
- MRI Brain without contrast (CPT® 70551) or with and without contrast (CPT® 70553) is medically necessary in all cases of open dysraphism as Chiari II malformation will be present
- Closed Dysraphism
  - MRI of the entire spine without contrast or without and with contrast is medically necessary at the time of initial diagnosis.
    - MRI Brain without contrast (CPT® 70551) or without and with contrast (CPT® 70553) or CT without contrast of the brain (CPT® 70450) is medically necessary in cases with associated hydrocephalus, signs of cerebral involvement, or the presence of multiple hydromyelia (which suggests hydrocephalus).
    - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72196) is medically necessary once if there are clinical signs of pelvic malformation or anorectal anomaly.
  - MRI Cervical, Thoracic, and Lumbar spine without contrast (CPT® 72141, 72146, 72148) or without and with contrast (CPT® 72156, 72157, 72158) is medically necessary when ordered for preoperative planning.
  - Spinal canal ultrasound (CPT® 76800) is medically necessary as an alternative to MRI, if requested, in individuals with open dysraphism as the posterior bony defect provides an acoustic window for ultrasound.
  - MRI of the appropriate spinal level without contrast or without and with contrast is medically necessary when there are new and/or worsened neurologic symptoms and/or physical exam findings suggestive of new or worsened tethering of the spinal cord, such as any of the following:
    - New or worsened cavus foot
    - New or worsened toe walking and/or upper motor neuron signs (including hyperreflexia, spasticity, and positive Babinski sign)
    - New or worsened leg weakness or numbness or difficulty in ambulation

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- New or worsened loss of perineal sensation
- New or worsened lower urinary tract dysfunction (including urinary urgency or urinary incontinence, or new or worse changes on diagnostic urodynamic studies)
- New or worsened constipation
- New or worsened pain in the back or legs suspected to have been caused by tethering of the spinal cord
  - MRI Brain without contrast (CPT® 70551) or without and with contrast (CPT® 70553) or CT without contrast of the brain (CPT® 70450) is medically necessary in cases with associated hydrocephalus, signs of cerebral involvement, or the presence of multiple hydromyelia (which suggests hydrocephalus).
  - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72196) is medically necessary once if there are clinical signs of pelvic malformation or anorectal anomaly.

◦ The appropriate spinal level, modality, and contrast level of follow-up advanced imaging will depend on the nature of the underlying disease, usually requested after specialist consultation.

General Guidelines - Other Congenital and Pediatric Spine Disorders (PEDSP-7.0)

SPP.CD.0007.0.A

v1.0.2026

- Many congenital spine disorders also affect adults as survival continues to improve for these individuals. Adults with disorders covered in this section may follow these guidelines except where contraindicated by specific statements in the general imaging guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Achondroplasia (PEDSP-7.1)

SPP.CD.0007.1.A

v1.0.2026

- The diagnosis of achondroplasia is made clinically. Individuals with achondroplasia are at risk for hydrocephalus as well as myelopathy from spinal stenosis with increasing age.
- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, and plain radiography should be performed prior to considering advanced imaging.
- MRI without contrast or without and with of the symptomatic spinal region is medically necessary when new or worsening clinical symptoms suggest achondroplasia-related spinal stenosis.
- MRI Brain without contrast (CPT® 70551) or CT Head without contrast (CPT® 70450) is medically necessary when new or worsening clinical symptoms suggest hydrocephalus.

Proprietary Information of UnitedHealthcare.

Inflammatory Spondylitis (PEDSP-7.2)

SPP.CD.0007.2.A

v1.0.2026

- Except as listed below, imaging considerations in pediatric and adult individuals are identical for this condition and these individuals should be imaged according to **Inflammatory Spondylitis (SP-10.2)**.

For pediatric individuals with juvenile idiopathic arthritis, the following imaging is medically necessary:

- MRI without and with contrast or without contrast of the involved levels
- An initial x-ray is not necessary prior to MRI in these individuals.
- For evaluation of facet arthropathy in patients with ankylosing spondylitis, osteoarthritis, or rheumatoid arthritis:
  - Whole body radiopharmaceutical localization imaging (CPT® 78802) and SPECT (CPT® 78803) OR
  - SPECT/CT (CPT® 78830)

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Atlantoaxial Instability in Trisomy 21 (Down Syndrome) (PEDSP-7.3)

SPP.CD.0007.3.A

v1.0.2026

- The diagnosis of atlantoaxial instability is a recognized complication of trisomy 21, and individuals are routinely screened with lateral x-rays of the cervical spine.
- MRI Cervical Spine without contrast (CPT® 72141) or without and with contrast (CPT® 72156) is medically necessary in individuals where the lateral cervical spine x-ray demonstrates an atlantodental (pre-dens) interval of ≥4.5 mm, and/or a neural canal width of ≤14 mm.
- MRI Cervical Spine without contrast (CPT® 72141) or without and with contrast (CPT® 72156) is medically necessary when new or worsening clinical symptoms suggest myelopathy in a trisomy 21 individual.

Click Here to Return to the Main TOC

Klippel-Feil Anomaly (Congenital Fusion of Cervical Vertebrae) (PEDSP-7.6)

SPP.CD.0007.6.A
v1.0.2026

This is generally an incidental finding. A detailed history and physical examination with thorough neurologic examination, and plain x-rays should be performed initially. Klippel-Feil can occur in conjunction with platybasia and/or Chiari malformation.

- Plain x-rays of the cervical spine are sufficient to establish the diagnosis. Advanced imaging is medically necessary if there are acute or worsening neurologic symptoms (including pain), or if multiple levels are involved.
  - MRI Cervical Spine without contrast (CPT® 72141) or CT Cervical Spine without contrast (CPT® 72125) for these indications.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Marfan Syndrome (PEDSP-7.7)

SPP.CD.0007.7.A
v1.0.2026

Individuals with Marfan syndrome are at risk for scoliosis (see **Scoliosis (PEDSP-3.2)**) and dural ectasias. Dural ectasias are usually asymptomatic but can be associated with other spinal lesions.

- A pertinent clinical evaluation including a detailed history, physical examination with thorough neurologic examination and documentation of any specific radicular features, and plain radiography should be performed prior to considering advanced imaging.
- MRI without contrast of the symptomatic spinal region is medically necessary for the following:
  - New or worsening clinical symptoms suggest a complicated dural ectasia.
  - The individual is under active consideration for surgery.

Proprietary Information of UnitedHealthcare.

Von Hippel-Lindau Syndrome (VHL) (PEDSP-7.9)

SPP.CD.0007.9.A

v1.0.2026

- See: **Von Hippel-Lindau Syndrome (VHL) (PEDONC-2.10)** in the Pediatric and Special Populations Oncology Imaging Guidelines for screening recommendations in VHL patients.
- MRI without and with contrast of the affected spinal level is medically necessary for individuals with known spinal hemangioblastomas in the following conditions:
  - Annually for asymptomatic individuals with unresected spinal hemangioblastoma(s).
  - Preoperative planning for resection of a hemangioblastoma.
  - New or worsening symptoms suggesting progression of a known hemangioblastoma.
